# Satellite Data

MHs are localised dropouts of the magnetic field accompanied by simultaneous increases in plasma density and pressure.

From Winterhalter et al (1994)

Bryan Simon

From Baumgärtel (1999)

Investigating Magnetic Holes

# Possible Creation Mechanisms I

## ■ Mirror Mode Structures

- Instability found in pressure anisotropic plasma
- However, the SW tends to be mirror stable
- Suggestion is that MHs are remnants of mirror-mode structures

## ■ DNLS Soliton

- DNLS Soliton model for magnetic holes derived from Hall-MHD
- Vorticity is a conserved quantity
- DNLS soliton solution for magnetic holes
- Consistent with experimental observations

# Possible Creation Mechanisms I

- Mirror Mode Structures
  - Instability found in pressure anisotropic plasma
  - However, the SW tends to be mirror stable
  - Suggestion is that MHs are remnants of mirror-mode structures
- DNLS Soliton
  - DNLS is an evolutionary equation derived from Hall-MHD
  - MHs signatures of DNLS soliton
  - DNLS not applicable in  $\beta \sim 1$  plasmas
  - Cannot tell us anything about stability

# Possible Creation Mechanisms I

## Possible Creation Mechanisms II

- RHP Alfvénic Wavepackets (AWP) and the Ponderomotive Force (PF)
  - Simulations by Buti et al. (2000) suggest that RHP AWP's collapse into MHs
  - Dynamic process supported by Hybrid Simulations
  - PF identified as important for strong pulses
  - PF accelerates particles perpendicular to wave propagation, so MHs could be caused by diamagnetic effects (Tsurutani et al, 2002)
- Slow mode solitons

## Model Premise

- Consider an 1.5D Hall-MHD model
- Move into time independent frame moving with a wave with speed  $M_A = v_x/v_A$  at an angle  $\theta$  to the magnetic field.
- Assume a polytropic equation of state

$$p_{\perp} = p_{\perp 0} n^{\gamma}$$

- Introduce an anisotropy parameter  $a_p$

$$a_p = \frac{p_{\parallel}}{p_{\perp}} - 1$$

- Use the spatially integrated momentum equation and the curl of Ohm's law

## Model Premise

- Consider an 1.5D Hall-MHD model
- Move into time independent frame moving with a wave with speed  $M_A = v_x/v_A$  at an angle  $\theta$  to the magnetic field.

- Use the spatially integrated momentum equation and the curl of Ohm's law

## Model Equations

$$0 = 2M_A^2 (n^{-1} - 1) + \beta (n^\gamma - 1) + b^2 - 1 + b_{x0}^2 a_p \beta (n^\gamma b^{-2} - 1)$$

$$\frac{\partial}{\partial s} b_y = f(b) - b_z g(b)$$

$$\frac{\partial}{\partial s} b_z = b_y g(b).$$

with

$$f(b) = b_{z0} n(b) \left[ 1 - \frac{1}{M_x^2} \left( 1 - \frac{a_p \beta}{2} \right) \right]$$

$$g(b) = 1 - \frac{n(b)}{M_x^2} \left( 1 - \frac{a_p \beta}{2} n^\gamma(b) b^{-2} \right)$$

System of 3 variables  $n, b_y, b_z$  and 5 parameters  $a_p, \beta, \gamma, \theta, M_A$

## Model Assumptions

- $M_A \ll 1$ , i.e. we are dealing slow moving structures and can write  $M_A = \varepsilon \bar{M}_A$ . This is supported by satellite data (e.g. Stasiewicz 2004)
- $\beta \sim 2$ . The spatial extent of MHs suggests that FLR effects are not important (Pogutse et al 1998)
- Oblique propagation angle but  $\theta \lesssim 85^\circ$
- $a_p$  stays constant over the structure.

## Model Assumptions

- $M_A \ll 1$ , i.e. we are dealing slow moving structures and can write  $M_A = \varepsilon \bar{M}_A$ . This is supported by satellite data (e.g. Stasiewicz 2004)
- $\beta \sim 2$ . The spatial extent of MHs suggests that FLR effects are not important (Pogutse et al 1998)
- Oblique propagation angle but  $\theta \lesssim 85^\circ$
- $a_p$  stays constant over the structure.

## Model Assumptions

- $M_A \ll 1$ , i.e. we are dealing slow moving structures and can write  $M_A = \varepsilon \bar{M}_A$ . This is supported by satellite data (e.g. Stasiewicz 2004)
- $\beta \sim 2$ . The spatial extent of MHs suggests that FLR effects are not important (Pogutse et al 1998)
- Oblique propagation angle but  $\theta \lesssim 85^\circ$
- $a_p$  stays constant over the structure.

We consider an  $O(1)$  expansion and search for fixed points.

## Model Assumptions

- $M_A \ll 1$ , i.e. we are dealing slow moving structures and can write  $M_A = \varepsilon \bar{M}_A$ . This is supported by satellite data (e.g. Stasiewicz 2004)
- $\beta \sim 2$ . The spatial extent of MHs suggests that FLR effects are not important (Pogutse et al 1998)
- Oblique propagation angle but  $\theta \lesssim 85^\circ$
- $a_p$  stays constant over the structure.

We can show  $b_y = 0$  at fixed points and label them as either centre or saddle

## Possible Solutions

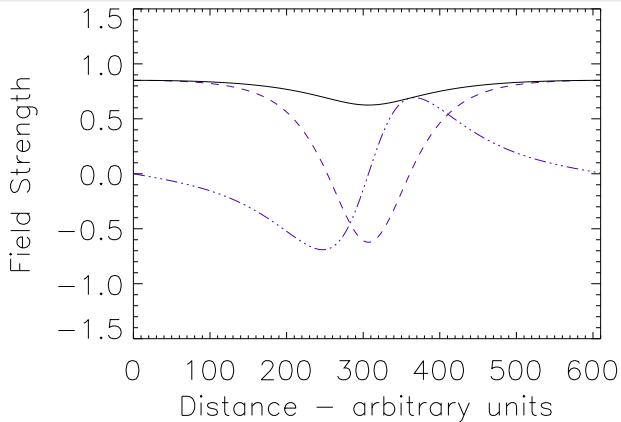

- Periodic wave solutions

## Possible Solutions

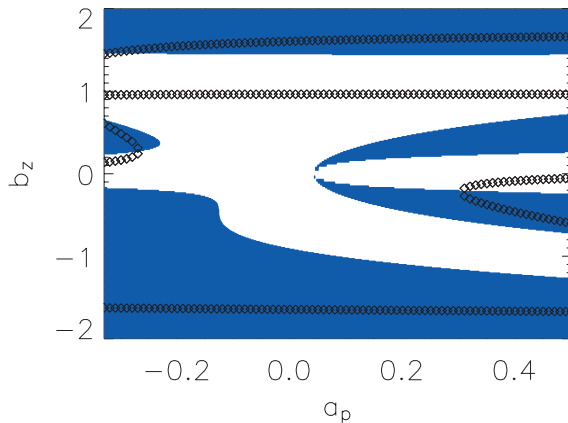

- Bright solitary wave solutions

## Possible Solutions

- Dark solitary wave solutions

# Pressure Anisotropy Dependence

From Simon and Rowlands (2007)

# Developing a Potential Formalism I

- The equations obtained from the curl of Ohm's law can be combined to derive an evolutionary equation for  $b$
- Introduce  $H(b) = \int bg(b)/f(b)db = b_z - b_{z0}$  and  $\tau = \int f(b)/bds$
- These substitutions yield

$$\begin{aligned}\frac{\partial^2 b}{\partial \tau^2} &= \left[ b - \frac{bg(b)H(b)}{f(b)} \right] - \frac{bb_{z0}g(b)}{f(b)} \\ &= F(b)\end{aligned}$$

- Mathematically equivalent to Newton II, so we can construct a pseudo-potential [Simon et al. (submitted)]

# Developing a Potential Formalism I

- These substitutions yield

$$\begin{aligned}\frac{\partial^2 b}{\partial \tau^2} &= \left[ b - \frac{bg(b)H(b)}{f(b)} \right] - \frac{bb_{z0}g(b)}{f(b)} \\ &= F(b)\end{aligned}$$

- Mathematically equivalent to Newton II, so we can construct a pseudo-potential [Simon et al. (submitted)]

$$V(b) = - \int F(b)db$$

# Developing a Potential Formalism I

- The equations obtained from the curl of Ohm's law can be combined to derive an evolutionary equation for  $b$
- Introduce  $H(b) = \int bg(b)/f(b)db = b_z - b_{z0}$  and  $\tau = \int f(b)/bds$
- These substitutions yield

$$\begin{aligned}\frac{\partial^2 b}{\partial \tau^2} &= \left[ b - \frac{bg(b)H(b)}{f(b)} \right] - \frac{bb_{z0}g(b)}{f(b)} \\ &= F(b)\end{aligned}$$

- Mathematically equivalent to Newton II, so we can construct a pseudo-potential [Simon et al. (submitted)]

$$V(b) = \frac{H(b)^2 - b^2}{2} + b_{z0}H(b)$$

# The $O(1)$ Approximation to the Potential

- In the case of slowly moving structures  $M_A = \varepsilon \bar{M}_A$ , one can show that

$$f(b) \approx \frac{b_{z0} b_{x0}^2 n}{\varepsilon \bar{M}_A} \left( \frac{a_p \beta}{2} - 1 \right)$$

$$g(b) \approx \frac{b_{x0}^2 n}{\varepsilon \bar{M}_A} \left( \frac{a_p \beta}{2} \frac{n^\gamma}{b^2} - 1 \right)$$

$$n^\gamma \approx \frac{b^2 [1 + \beta (1 + a_p b_{x0}^2) - b^2]}{\beta (b^2 + a_p b_{x0}^2)}$$

- In this case, one can approximate  $H(b)$  by

$$H(b) = \frac{1}{b_{z0} \left( \frac{a_p \beta}{2} - 1 \right)} \int b \left( \frac{a_p}{2} \frac{[1 + \beta (1 + a_p b_{x0}^2) - b^2]}{b^2 + a_p b_{x0}^2} - 1 \right) db$$

# The $O(1)$ Approximation to the Potential

- In the case of slowly moving structures  $M_A = \varepsilon \bar{M}_A$ , one can show that

$$f(b) \approx \frac{b_{z0} b_{x0}^2 n}{\varepsilon \bar{M}_A} \left( \frac{a_p \beta}{2} - 1 \right)$$

$$g(b) \approx \frac{b_{x0}^2 n}{\varepsilon \bar{M}_A} \left( \frac{a_p \beta}{2} \frac{n^\gamma}{b^2} - 1 \right)$$

$$n^\gamma \approx \frac{b^2 [1 + \beta (1 + a_p b_{x0}^2) - b^2]}{\beta (b^2 + a_p b_{x0}^2)}$$

- In this case, one can approximate  $H(b)$  by

$$H(b) = \frac{1}{b_{z0} \left( \frac{a_p \beta}{2} - 1 \right)} \int b \left( \frac{a_p}{2} \frac{[1 + \beta (1 + a_p b_{x0}^2) - b^2]}{b^2 + a_p b_{x0}^2} - 1 \right) db$$

## General Potential Considerations

- $H(b)$  can be used to calculate the Sagdeev potential for this problem
- Periodic wave solutions would correspond to oscillations about a potential minimum
- Solitary wave solutions exist around a potential maximum/minimum

Comparison  $O(1)$  and Numerical Potential

Comparison  $O(1)$  and Numerical Potential

Comparison  $O(1)$  and Numerical Potential

# Comparison $O(1)$ and Numerical Potential

# Stability of Solutions

- All analysis so far has been performed in a time independent frame, so one can say nothing about stability
- To consider the stability, one can
  - try to solve the time dependent equations mathematically
  - run numerical simulations
- Mathematical Analysis suggests that under certain approximations solitary wave solutions should be stable.
- To check this, we are running hybrid simulations.

## Hybrid Code Description

- 1.5D hybrid code with ion particles and fluid electrons.  
Contains periodic boundary conditions.
- Allows us to introduce ion-particle effects
- Based on Winske (1985)
- Uses massless fluid energy equation to close system of equations.

## The case for Full Kinetic Treatment

- Hybrid simulations can include some kinetic effects, but assume that the electron kinetic effects are unimportant.
- Lin et al (1995) found evidence of Langmuir wave creation in the holes. The suggestion is that these waves are created by electron beams.
- To investigate this phenomenon computationally, one would require a full PIC simulation.

# Conclusions

- We present slow mode solitary wave solutions to Hall-MHD which are possible candidates for MHs
- We derive a pseudo potential description which explains solitary waves as local potential max/min combinations
- We are currently performing hybrid simulations to investigate the predicted stability of these structures
- In order to fully explain some aspects of MHs, such as Langmuir wave excitation, one would need a fully kinetic code
