

# Indian Buffet Epidemics

A non-parametric Bayesian Approach to Modelling  
Heterogeneity

Ashley Ford, Gareth Roberts

Department of Statistics, University of Warwick

Inference For Epidemic-related Risk, 2011

# Outline

Bipartite Graph Epidemic models

Inference for bipartite epidemic models

Indian Buffet Process

Indian Buffet Epidemics

# Motivation

- ▶ Need a model between
  - ▶ homogeneous mixing
  - ▶ over complex models with unknown parameters.
- ▶ Many have been proposed
  - ▶ household, spatial, multi-type
- ▶ Availability of data
  - ▶ contact surveys
    - ▶ RFID
    - ▶ POLYMOD
  - ▶ commuting data
- ▶ A non-parametric model for the heterogeneity that can represent a wide range of departures from homogeneity.

# Motivation

- ▶ Need a model between
  - ▶ homogeneous mixing
  - ▶ over complex models with unknown parameters.
- ▶ Many have been proposed
  - ▶ household, spatial, multi-type
- ▶ Availability of data
  - ▶ contact surveys
    - ▶ RFID
    - ▶ POLYMOD
  - ▶ commuting data
- ▶ A non-parametric model for the heterogeneity that can represent a wide range of departures from homogeneity.

  - ▶ commuting data
- ▶ A non-parametric model for the heterogeneity that can represent a wide range of departures from homogeneity.

# Places and People

- ▶ Model heterogeneity in an epidemic amongst  $N$  people
- ▶ Each person belongs to 1 or more of many classes
  - ▶ e.g. households, schools, clubs, buses etcetera
- ▶ represented as
  - ▶ a bipartite graph
  - ▶ an  $N \times K$  binary matrix  $Z$

# Places and People

- ▶ Model heterogeneity in an epidemic amongst  $N$  people

# Epidemics on bipartite graphs

Extend homogeneous mixing epidemic models to bipartite graph

- ▶ e.g. SIR, SEIR, SIS, Reed-Frost

Approaches to defining the infection rate

- ▶ a single infection rate could apply to all pairs of individuals connected through one or more locations
- ▶ Each class has an associated infection rate  $\lambda_k$
- ▶ Rate of infections on a susceptible individual  $j$  is  $\sum z_{jk} \lambda_k N_{k,t}^I$ 
  - ▶  $N_{k,t}^I$  is the number that are in class  $k$  and infective at time  $t$ .

# Simulation

# Household epidemic models

Global and within household infection rates  $\lambda_g$  and  $\lambda_h$

household size  $m$

number of households  $n_h$

a bipartite graph representation with adjacency matrix  $N \times (n_h + 1)$  where  $N = n_h m$

e.g. for 4 houses of sizes 2,3,3,4 the adjacency matrix is

$\lambda_g$	$\lambda_h$	$\lambda_h$	$\lambda_h$	$\lambda_h$

# Multi-type model

A multi-type model with infection rate  $\gamma_{i,j}$  between an infective in group  $i$  and a susceptible in group  $j$ .

If  $\gamma_{i,j} = \gamma_{j,i}$  and  $\sum_{j \neq i} \gamma_{i,j} \leq \gamma_{i,i} \forall i$  it can be represented as a bipartite model.

These conditions will usually apply if the groups are geographically separate,

but may not if the groups are split by ages or varying susceptibility and infectiousness e.g.  $\gamma_{i,j} = \alpha_i \beta_j$ .

With  $m$  types the bipartite representation has  $m$  columns for the within type infections and  $m(m-1)/2$  for the between type infections.

## Multi-type model

A multi-type model with infection rate  $\gamma_{i,j}$  between an infective in group  $i$  and a susceptible in group  $j$ .

If  $\gamma_{i,j} = \gamma_{j,i}$  and  $\sum_{j \neq i} \gamma_{i,j} \leq \gamma_{i,i} \forall i$  it can be represented as a bipartite model.

These conditions will usually apply if the groups are geographically separate,

but may not if the groups are split by ages or varying susceptibility and infectiousness e.g.  $\gamma_{i,j} = \alpha_i \beta_j$ .

With  $m$  types the bipartite representation has  $m$  columns for the within type infections and  $m(m-1)/2$  for the between type infections.

# Multi-type model

$\gamma_{1,1} - \gamma_{1,2} - \gamma_{1,3}$	$\gamma_{2,2} - \gamma_{1,2} - \gamma_{2,3}$	$\gamma_{3,3} - \gamma_{1,3} - \gamma_{2,3}$	$\gamma_{1,2}$	$\gamma_{1,3}$	$\gamma_{2,3}$
1			1	1

## Examples

# Other Models

- ▶ three level
- ▶ commuting
- ▶ known labels

## MCMC inference for known contact matrix

log likelihood when observed on  $[0, T_{\max}]$   
with  $n$  infections at  $T_j^I$  and removals at  $T_j^R$

$$\sum_j \log \eta_j(T_j^I) - \int_0^{T_{\max}} \sum_j \eta_j(t) dt + \sum_j \log g(T_j^R - T_j^I) + \sum_j \log \{1 - G(T_{\max} - T_j^I)\}$$

where  $\eta_j(t) = \sum_k z_{jk} \lambda_k N_{k,t-}^I$  is the instantaneous rate of infections on individual  $j$ ,  $g$  and  $G$  are the pdf and cdf of time to recovery. A simulation with  $Z 1000 \times 21$  and  $\lambda_k = .5/n_k$  has 626 infections

# MCMC inference for known contact matrix

RW - Metropolis-Hastings for 21 parameters

true values 0.00058, 0.00150, 0.17000

# non-parametric inference

- ▶ Parametric distributions
  - ▶ Gaussian, Cauchy
  - ▶ exponential, gamma, log-normal, Weibull
- ▶ Non-parametric
  - ▶ histograms
  - ▶ kernel density estimate

# Indian Buffet Process- a culinary metaphor

Introduced by Griffiths and Ghahramani (2005) .

- ▶  $N$  customers enter a restaurant one after another.
- ▶ The first customer selects  $\text{Poisson}(\alpha)$
- ▶ The  $j$ th customer selects each dish with probability  $m_k/j$ 
  - ▶ where  $m_k$  is the number of previous customers who have chosen  $k$ .
- ▶ and then tries  $\text{Poisson}(\alpha/j)$  new dishes.

A distribution over all binary matrices with  $N$  rows

- ▶ Expected number in each row is  $\alpha$
- ▶ Expected number of non zero columns  $\alpha \sum_j^N 1/j$

# Indian Buffet Process - example

IBP  $Z$  generated with  $N = 260$ ,  $\alpha = 15$

## Limit of Finite $K$

- ▶  $\psi_k$  is the probability that an individual is in class  $k$
- ▶  $\psi_k \sim \text{Beta}(\alpha/K, 1)$  or from stick breaking
- ▶ The model for  $Z$  is:  $z_{ik} | \psi_k \sim \text{Bernoulli}(\psi_k)$  independently
- ▶ The Indian Buffet process is obtained as  $K \rightarrow \infty$

# Indian Buffet Epidemic

Combine the bipartite graph model with the Indian Buffet Process as a prior for the contact graph.

$\alpha = 6$ ,  $N = 600$ ,  $K_+ = 31$ , different initial infectives in 8, 4, 1

# MCMC for Indian Buffet Epidemic

- ▶ A challenging MCMC problem
  - ▶ Very high dimensional
  - ▶ multi-modal
- ▶ Proposals
  - ▶ non centered, using fixed  $K$
  - ▶ independence, using sequential IBP

Posterior using true Z

marginal posterior, mcmc Z

# Conclusions

- ▶ Bi-partite graph epidemics provide a generic formulation for modeling and inference.
- ▶ The Indian Buffet Epidemic provides a non-parametric model for heterogeneity in contact processes.
- ▶ MCMC inference is possible on small epidemics
  - ▶ Work continues on extending the size which can be handled
