# Lévy moving average processes

- We consider a *Lévy moving average* process

$$X_t = X_0 + \int_{-\infty}^t g(t-s) dL_s,$$

where  $L$  is a pure jump Lévy process and the function  $g$  is assumed to be of the form

$$g(x) = x^\alpha f(x), \quad \alpha > 0,$$

with  $f : \mathbb{R}^+ \rightarrow \mathbb{R}$  being a smooth exponentially decaying function with  $f(0) \neq 0$ .

- Since  $\alpha > 0$  the process  $X$  turns out to be continuous and stationary.

# Power variations

- We define the  $k$ th order differences of  $X$  via

$$\Delta_{i,k}^n X := \sum_{j=0}^k (-1)^j \binom{k}{j} X_{(i-j)/n}.$$

For instance,

$$\Delta_{i,1}^n X = X_{i/n} - X_{(i-1)/n} \quad \text{and} \quad \Delta_{i,2}^n X = X_{i/n} - 2X_{(i-1)/n} + X_{(i-2)/n}.$$

- The power variation of  $k$ th order differences of  $X$  is given by the statistic

$$V(X, p, k)_n := \sum_{i=k}^n |\Delta_{i,k}^n X|^p.$$

In the following we will study the asymptotic behaviour of the functional  $V(X, p, k)_n$ .

# Background on Lévy processes

- Lévy motions are stochastic processes with *stationary* and *independent* increments, which are *continuous in probability*.
- A *pure jump Lévy process*  $L$  with Lévy measure  $\nu$  and drift  $\gamma$  has the characteristic function

$$\mathbb{E}[\exp(iuL_t)] = \exp(t\psi(u))$$

with

$$\psi(u) = \gamma u + \int_{\mathbb{R} \setminus \{0\}} (\exp(iux) - 1 - iux \mathbf{1}_{\{|x| \leq 1\}}) \nu(dx).$$

# Blumenthal-Gettoor index

- Let  $\Delta L_s = L_s - L_{s-}$  denote the jump of  $L$  at time  $s$ . The Blumenthal-Gettoor index  $\beta$  is defined as

$$\begin{aligned}\beta &:= \inf \left\{ r \geq 0 : \int_{-1}^1 |x|^r \nu(dx) < \infty \right\} \\ &= \inf \left\{ r \geq 0 : \sum_{s \in [0,1]} |\Delta L_s|^r < \infty \right\}.\end{aligned}$$

- For all Lévy processes it holds that

$$\sum_{s \in [0,1]} |\Delta L_s|^2 < \infty.$$

Hence,  $\beta \in [0, 2]$ .

# Symmetric $\beta$ -stable Lévy processes

- A symmetric  $\beta$ -stable Lévy process (S $\beta$ S) has a Lévy measure of the form

$$\nu(dx) = \text{const} \cdot |x|^{-1-\beta} dx, \quad \beta \in (0, 2).$$

Such a process is self-similar with index  $1/\beta$ , i.e.

$$(L_{at})_{t \geq 0} \stackrel{d}{=} (a^{1/\beta} L_t)_{t \geq 0}$$

- For  $\beta$ -stable Lévy processes it holds that

$\beta =$  Blumenthal-Gettoor index.

# Assumptions on $X_t = X_0 + \int_{-\infty}^t g(t-s)dL_s$

Assumption (A):

(i)  $g(x) = x^\alpha f(x)$  with  $\alpha > 0$  and  $f(0) \neq 0$ .

(ii) For some  $\theta > 0$  it holds that

$$\limsup_{t \rightarrow \infty} t^\theta \nu\{x : |x| > t\} < \infty$$

(iii)  $g \in C^k(\mathbb{R}_{\geq 0})$ ,

$$|g^{(j)}(x)| \leq K|x|^{\alpha-j}, \quad x \in (0, \delta)$$

and  $g^{(j)} \in L^\theta((\delta, \infty))$  for some  $\delta > 0$ . Moreover,  $|g^{(j)}|$  is decreasing on  $(\delta, \infty)$ .

# Remarks

- Assumption (A) guarantees the existence of the integrals

$$\int_{-\infty}^t g(t-s)dL_s \quad \text{and} \quad \int_{-\infty}^{t-\varepsilon} g^{(k)}(t-s)dL_s,$$

for any  $\varepsilon > 0$ , where  $k$  is the order of increments of  $X$ . The symmetry of  $L$  is not essential for most parts of the limit theory.

- We will see that the limit theory for power variation  $V(X, p, k)_n = \sum_{i=k}^n |\Delta_{i,k}^n X|^p$  gives quite surprising results. In particular, it depends on the interplay between the parameters  $k$ ,  $p$ ,  $\alpha$  and  $\beta$ .
- Only case (ii) below appeared in an earlier paper by Benassi, Cohen and Istas (04). However, their proof was incorrect.

# First order asymptotics for $V(X, p, k)_n = \sum_{i=k}^n |\Delta_{i,k}^n X|^p$

**Theorem:** Assume that assumption (A) holds and  $L$  is a pure jump Lévy process with Blumenthal-Gettoor index  $\beta \in (0, 2)$ .

(i) If  $\alpha \in (0, k - 1/p)$  and  $p > \beta$ , we obtain

$$n^{\alpha p} V(X, p, k)_n \xrightarrow{d_{st}} |f(0)|^p \sum_{m: T_m \in [0, 1]} |\Delta L_{T_m}|^p \left( \sum_{l=k}^{\infty} |h_k(l + U_m)|^p \right),$$

where  $(T_m)$  are jump times of  $L$ ,  $(U_m)_{m \geq 1}$  is a sequence of iid  $\mathcal{U}([0, 1])$ -distributed random variables and the function  $h_k$  is defined via

$$h_k(x) := \sum_{j=0}^k (-1)^j \binom{k}{j} (x - j)_+^{\alpha}.$$

# First order asymptotics for power variation

## Theorem (cont.):

(ii) Assume that  $L$  is a  $S\beta S$  process with  $\beta \in (0, 2)$ . If  $\alpha \in (0, k - 1/\beta)$  and  $p < \beta$ , we obtain

$$n^{p(\alpha+1/\beta)-1} V(X, p, k)_n \xrightarrow{\mathbb{P}} \mathbb{E}[|\tilde{L}_1^{(k)}|^p]$$

where  $\tilde{L}^{(k)}$  is a  $S\beta S$  process defined via

$$\tilde{L}_t^{(k)} := f(0) \int_{\mathbb{R}} h_k(t-s) dL_s.$$

When  $k = 1$ ,  $\tilde{L}_t^{(1)} = f(0) \int_{\mathbb{R}} [(t-s)_+^\alpha - (t-s-1)_+^\alpha] dL_s$  is a *fractional  $\beta$ -stable Lévy noise*.

# First order asymptotics for power variation

## Theorem (cont.):

(iii) If  $\alpha > k - 1/p$ ,  $p > \beta$  or  $\alpha > k - 1/\beta$ ,  $p < \beta$ , we deduce

$$n^{kp-1} V(X, p, k)_n \xrightarrow{\mathbb{P}} \int_0^1 |F_s^{(k)}|^p ds$$

with

$$F_s^{(k)} = \int_{-\infty}^s g^{(k)}(s-u) dL_u.$$

# Critical cases

## Theorem (cont.):

(iv) If  $\alpha = k - 1/p$  and  $p > \beta$ , we obtain

$$\frac{n^{\alpha p}}{\log n} V(X, p, k)_n \xrightarrow{\mathbb{P}} |f(\circ)|^p \sum_{m: T_m \in [0,1]} |\Delta L_{T_m}|^p$$

(v) Assume that  $L$  is a S $\beta$ S process with  $\beta \in (0, 2)$ . If  $\alpha = k - 1/\beta$  and  $p < \beta/2$ , we obtain

$$\frac{n^{p(\alpha+1/\beta)-1}}{(\log n)^{p/\beta}} V(X, p, k)_n \xrightarrow{\mathbb{P}} c_p^k$$

for a certain constant  $c_p^k$ .

# Summary of first order asymptotics

## Theorem:

(i) If  $\alpha \in (0, k - 1/p)$  and  $p > \beta$ , we obtain

$$n^{\alpha p} V(X, p, k)_n \xrightarrow{d_{st}} |f(0)|^p \sum_{m: T_m \in [0, 1]} |\Delta L_{T_m}|^p \left( \sum_{l=k}^{\infty} |h_k(l + U_m)|^p \right),$$

(ii) Assume that  $L$  is a S $\beta$ S process with  $\beta \in (0, 2)$ . If  $\alpha \in (0, k - 1/\beta)$  and  $p < \beta$ , we obtain

$$n^{p(\alpha + 1/\beta) - 1} V(X, p, k)_n \xrightarrow{\mathbb{P}} \mathbb{E}[|\tilde{L}_1^{(k)}|^p]$$

(iii) If  $\alpha > k - 1/p$ ,  $p > \beta$  or  $\alpha > k - 1/\beta$ ,  $p < \beta$ , we deduce

$$n^{kp-1} V(X, p, k)_n \xrightarrow{\mathbb{P}} \int_0^1 |F_s^{(k)}|^p ds \quad \text{with} \quad F_s^{(k)} = \int_{-\infty}^s g^{(k)}(s-u) dL_u.$$

# Remarks

- The rate of convergence in cases (i)-(iii) uniquely identifies the parameters  $\alpha$  and  $\beta$ . This might be useful for statistical applications.
- Cases (ii) and (iii) can be extended to a functional convergence. Case (i) is more problematic.
- Also extensions to Lévy semi-stationary processes with non-trivial intermittency  $\sigma$  are in most cases relatively straightforward.
- Cases (i) and (iii) can be probably extended to general pure jump semimartingale drivers  $L$ .

## Remarks

- Recall the convergence in case (i): If  $\alpha \in (0, k - 1/p)$  and  $p > \beta$ , we obtain

$$n^{\alpha p} V(X, p, k)_n \xrightarrow{d_{st}} |f(0)|^p \sum_{m: T_m \in [0,1]} |\Delta L_{T_m}|^p \left( \sum_{l=k}^{\infty} |h_k(l + U_m)|^p \right),$$

- The conditions  $\alpha \in (0, k - 1/p)$  and  $p > \beta$  are essentially sharp. Indeed, since  $|h(x)| \leq Cx^{\alpha-k}$  for  $x$  large, we deduce that

$$\sum_{l=k}^{\infty} |h_k(l + U_m)|^p \leq \text{const} < \infty \iff \alpha < k - 1/p.$$

On the other hand, it holds that

$$\sum_{m: T_m \in [0,1]} |\Delta L_{T_m}|^p < \infty,$$

since  $\beta$  is the Blumenthal-Gettoor index of  $L$  and  $p > \beta$ .

## Sketch of proof: Case (ii)

- Assume for the moment that  $k = 1$ . We first show the approximation

$$\begin{aligned} X_{i/n} - X_{(i-1)/n} &\approx f(0) \int_{\mathbb{R}} [(i/n - s)_+^\alpha - ((i-1)/n - s)_+^\alpha] dL_s \\ &\stackrel{d}{=} n^{-(\alpha+1/\beta)} f(0) \int_{\mathbb{R}} [(i - s)_+^\alpha - (i-1 - s)_+^\alpha] dL_s, \end{aligned}$$

where the latter is a fractional  $\beta$ -stable Lévy noise, which is  $(\alpha + 1/\beta)$ -self similar. In a second step we apply the ergodic theorem.

- Another idea of proof, which usually requires existence of second moments (i.e.  $p < \beta/2$ ), relies on the identity

$$|x|^p = a_p^{-1} \int_{\mathbb{R}} \frac{\exp(iux) - 1}{|u|^{1+p}} du, \quad p \in (0, 1),$$

and  $a_p = \int_{\mathbb{R}} \frac{\exp(iu) - 1}{|u|^{1+p}} du$ . This identity connects the  $p$ th power with characteristic function.

## Sketch of proof: Case (i)

- Assume for the moment that  $k = 1$  and the Lévy process  $L$  has a single jump at time  $T \in [0, 1]$ . Let  $j$  be a random index such that

$$T \in [(j-1)/n, j/n)$$

- We first show the approximation

$$\begin{aligned} X_{i/n} - X_{(i-1)/n} &\approx \int_{(i-1)/n}^{i/n} g(i/n - s) dL_s \\ &+ \int_0^{(i-1)/n} [g(i/n - s) - g((i-1)/n - s)] dL_s \\ &:= A_i^n + B_i^n \end{aligned}$$

## Sketch of proof: Case (i)

- Since  $T \in [(j-1)/n, j/n)$  we have that

$$\begin{aligned}A_i^n \neq 0 &\iff i = j, \\B_i^n \neq 0 &\iff i > j.\end{aligned}$$

- Now, it holds that

$$\begin{aligned}|A_j^n|^p &= \left| \int_{(j-1)/n}^{j/n} g(j/n - s) dL_s \right|^p = |\Delta L_T|^p |g(j/n - T)|^p \\&\approx |f(0) \Delta L_T|^p (j/n - T)^{\alpha p} \stackrel{d}{=} n^{-\alpha p} |f(0) \Delta L_T|^p U^{\alpha p},\end{aligned}$$

where  $U \sim \mathcal{U}([0, 1])$ . Similarly, it follows that ( $l \geq 1$ )

$$|B_{j+l}^n|^p \stackrel{d}{\approx} n^{-\alpha p} |f(0) \Delta L_T|^p ((l+U)^\alpha - (l-1+U)^\alpha)^p.$$

## Second order asymptotics associated with case (ii)

**Theorem:** Assume that  $L$  is a  $S\beta S$  process with  $\beta \in (0, 2)$ .

(1) When  $k \geq 2$ ,  $\alpha \in (0, k - 2/\beta)$  and  $p < \beta/2$ , we obtain

$$\sqrt{n} \left( n^{p(\alpha+1/\beta)-1} V(X, p, k)_n - \mathbb{E}[\tilde{L}_1^{(k)} |^p] \right) \Longrightarrow \mathcal{N}(0, v^2).$$

(2) When  $k = 1$ ,  $\alpha \in (0, 1 - 1/\beta)$  and  $p < \beta/2$ , it holds that

$$n^{1 - \frac{1}{(1-\alpha)\beta}} \left( n^{p(\alpha+1/\beta)-1} V(X, p, k)_n - \mathbb{E}[\tilde{L}_1^{(k)} |^p] \right) \Longrightarrow S^{(1-\alpha)\beta},$$

where  $S^{(1-\alpha)\beta}$  is a  $S(1 - \alpha)\beta S$  random variable.

Remark: Part (2) uses the methods of Surgailis (04) established for discrete moving average processes.

Thank you!
