(KILLED) LÉVY PROCESS

• (ξ_t, t ≥ 0) is a (killed) Lévy process if it has stationary and independents with RCLL paths (and is sent to a cemetery state after and independent and exponentially distributed time).

§1.	§2.	§3.	§4.	§5.	§6.	Exercises.
●00000	0000000000000	0000	00000000000000	00000	00000000000000	000

(KILLED) LÉVY PROCESS

- (ξ_t, t ≥ 0) is a (killed) Lévy process if it has stationary and independents with RCLL paths (and is sent to a cemetery state after and independent and exponentially distributed time).
- Process is entirely characterised by its one-dimensional transitions, which are coded by the Lévy–Khinchine formula

$$\mathbf{E}[\mathbf{e}^{\mathbf{i}\boldsymbol{\theta}\cdot\boldsymbol{\xi}_t}] = \mathbf{e}^{-\Psi(\boldsymbol{\theta})t}, \qquad \boldsymbol{\theta} \in \mathbb{R}^d,$$

where,

$$\Psi(\theta) = q + \mathrm{i} \mathbf{a} \cdot \theta + \frac{1}{2} \theta \cdot \mathbf{A} \theta + \int_{\mathbb{R}^d} (1 - \mathrm{e}^{\mathrm{i} \theta \cdot x} + \mathrm{i} (\theta \cdot x) \mathbf{1}_{(|x| < 1)}) \Pi(\mathrm{d} x),$$

where $a \in \mathbb{R}$, **A** is a $d \times d$ Gaussian covariance matrix and Π is a measure satisfying $\int_{\mathbb{R}^d} (1 \wedge |x|^2) \Pi(dx) < \infty$. Think of Π as the intensity of jumps in the sense of

P(X has jump at time *t* of size dx) = $\Pi(dx)dt + o(dt)$.

(KILLED) LÉVY PROCESS

- (ξ_t, t ≥ 0) is a (killed) Lévy process if it has stationary and independents with RCLL paths (and is sent to a cemetery state after and independent and exponentially distributed time).
- Process is entirely characterised by its one-dimensional transitions, which are coded by the Lévy–Khinchine formula

$$\mathbf{E}[\mathbf{e}^{\mathbf{i}\boldsymbol{\theta}\cdot\boldsymbol{\xi}_t}] = \mathbf{e}^{-\Psi(\boldsymbol{\theta})t}, \qquad \boldsymbol{\theta} \in \mathbb{R}^d,$$

where,

$$\Psi(\theta) = q + \mathrm{i} \mathbf{a} \cdot \theta + \frac{1}{2} \theta \cdot \mathbf{A} \theta + \int_{\mathbb{R}^d} (1 - \mathrm{e}^{\mathrm{i} \theta \cdot x} + \mathrm{i} (\theta \cdot x) \mathbf{1}_{(|x| < 1)}) \Pi(\mathrm{d} x),$$

where $a \in \mathbb{R}$, **A** is a $d \times d$ Gaussian covariance matrix and Π is a measure satisfying $\int_{\mathbb{R}^d} (1 \wedge |x|^2) \Pi(dx) < \infty$. Think of Π as the intensity of jumps in the sense of

 $\mathbf{P}(X \text{ has jump at time } t \text{ of size } dx) = \Pi(dx)dt + o(dt).$

In one dimension the path of a Lévy process can be monotone, in which case it is called a *subordinator* and we work with the Laplace exponent

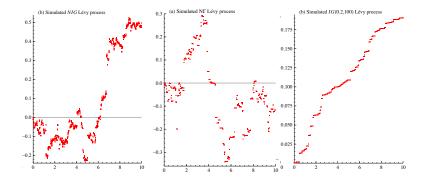

$$\mathbf{E}[\mathrm{e}^{-\lambda\xi_t}] = \mathrm{e}^{-\Phi(\lambda)t}, \qquad t \ge 0$$

where

$$\Phi(\lambda) = q + \delta \lambda + \int_{(0,\infty)} (1 - e^{-\lambda x}) \Upsilon(\mathrm{d}x), \qquad \lambda \ge 0.$$

FIRST ENTRY TO (x, ∞)

- ► Recall Wiener–Hopf factorisation $\Psi(\theta) = \kappa(-i\theta)\hat{\kappa}(i\theta), \quad \theta \in \mathbb{R}$., where κ and $\hat{\kappa}$ are Laplace exponents of subordinators.
- Associated to $\hat{\kappa}$ and $\hat{\kappa}$ are their potentials

$$\int_{[0,\infty)} e^{-\beta x} U(dx) = \frac{1}{\kappa(\beta)} \quad \text{and} \quad \int_{[0,\infty)} e^{-\beta x} \hat{U}(dx) = \frac{1}{\hat{\kappa}(\beta)}, \qquad \beta \ge 0.$$

Theorem (Triple law at first entry to (x, ∞)) Recall $\tau_x^+ = \inf\{t > 0 : \xi_t > x\}$. For $u > 0, v \ge y, y \in [0, x]$,

$$\mathbb{P}(\xi_{\tau_x^+} - x \in \mathrm{d} u, \, x - \xi_{\tau_x^+} \in \mathrm{d} v, \, x - \bar{\xi}_{\tau_x^+} \in \mathrm{d} y) = U(x - \mathrm{d} y)\hat{U}(\mathrm{d} v - y)\Pi(\mathrm{d} u + v).$$

Creeping is one way to hit a point, but not the only way

Theorem (Kesten (1969)/Bretagnolle (1971))

Suppose that ξ is not a compound Poisson process. Then ξ can hit points if and only if

$$\int_{\mathbb{R}} \operatorname{Re}\left(\frac{1}{1+\Psi(z)}\right) \mathrm{d} z < \infty.$$

If the Kesten-Bretagnolle integral test is satisfied, then

$$\mathbb{P}(\tau^{\{x\}} < \infty) = \frac{u(x)}{u(0)},$$

where $\tau^{\{x\}} = \inf\{t > 0 : \xi_t = x\}$, providing we can compute the inversion

$$u(x) = \int_{c+i\mathbb{R}} \frac{e^{-zx}}{\Psi(-iz)} dz$$

for some $c \in \mathbb{R}$.

§2. Self-similar Markov processes

Self-Similar Markov processes (SSMP)

Definition

A regular strong Markov process $(Z_t : t \ge 0)$ on \mathbb{R}^d , with probabilities $\mathbb{P}_x, x \in \mathbb{R}^d$, is a rssMp if there exists an index $\alpha \in (0, \infty)$ such that for all c > 0 and $x \in \mathbb{R}^d$,

 $(cZ_{tc^{-\alpha}}: t \ge 0)$ under \mathbb{P}_x is equal in law to $(Z_t: t \ge 0)$ under \mathbb{P}_{cx} .

• Write $\mathcal{N}_d(\mathbf{0}, \boldsymbol{\Sigma})$ for the Normal distribution with mean $\mathbf{0} \in \mathbb{R}^d$ and correlation (matrix) $\boldsymbol{\Sigma}$. The moment generating function of $X_t \sim \mathcal{N}_d(\mathbf{0}, \boldsymbol{\Sigma}t)$ satisfies, for $\theta \in \mathbb{R}^d$,

$$\mathbf{E}[\mathbf{e}^{\theta \cdot X_t}] = \mathbf{e}^{t\theta^{\mathrm{T}} \boldsymbol{\Sigma} \theta/2} = \mathbf{e}^{(c^{-2}t)(c\theta)^{\mathrm{T}} \boldsymbol{\Sigma}(c\theta)/2} = E[\mathbf{e}^{\theta \cdot cX_c - 2_t}].$$

Thinking about the stationary and independent increments of Brownian motion, this can be used to show that \mathbb{R}^d -Brownian motion: is a ssMp with $\alpha = 2$.

Suppose that $(X_t : t \ge 0)$ is an \mathbb{R} -Brownian motion:

▶ Write $\underline{X}_t := \inf_{s < t} X_s$. Then (X_t, \underline{X}_t) , $t \ge 0$ is a Markov process.

Suppose that $(X_t : t \ge 0)$ is an \mathbb{R} -Brownian motion:

- ▶ Write $\underline{X}_t := \inf_{s \leq t} X_s$. Then (X_t, \underline{X}_t) , $t \geq 0$ is a Markov process.
- For *c* > 0 and *α* = 2,

$$\binom{c\underline{X}_{c}-\alpha_{t}}{cX_{c}-\alpha_{t}} = \binom{c\inf_{s\leq c-\alpha_{t}}X_{s}}{cX_{c}-\alpha_{t}} = \binom{\inf_{u\leq t}cX_{c}-\alpha_{u}}{cX_{c}-\alpha_{t}}, \quad t\geq 0,$$

and the latter is equal in law to (X, \underline{X}) , because of the scaling property of X.

Suppose that $(X_t : t \ge 0)$ is an \mathbb{R} -Brownian motion:

- ▶ Write $\underline{X}_t := \inf_{s \leq t} X_s$. Then (X_t, \underline{X}_t) , $t \geq 0$ is a Markov process.
- For *c* > 0 and *α* = 2,

$$\binom{c\underline{X}_{c-\alpha_{t}}}{cX_{c-\alpha_{t}}} = \binom{c\inf_{s \leq c-\alpha_{t}} X_{s}}{cX_{c-\alpha_{t}}} = \binom{\inf_{u \leq t} cX_{c-\alpha_{u}}}{cX_{c-\alpha_{t}}}, \quad t \geq 0,$$

and the latter is equal in law to (X, \underline{X}) , because of the scaling property of X.

▶ Markov process $Z_t := X_t - (-x \land \underline{X}_t), t \ge 0$ is also a ssMp on $[0, \infty)$ issued from x > 0 with index 2.

Suppose that $(X_t : t \ge 0)$ is an \mathbb{R} -Brownian motion:

- ▶ Write $\underline{X}_t := \inf_{s \le t} X_s$. Then (X_t, \underline{X}_t) , $t \ge 0$ is a Markov process.
- For *c* > 0 and *α* = 2,

$$\binom{c\underline{X}_{c^{-\alpha}t}}{cX_{c^{-\alpha}t}} = \binom{c\inf_{s \le c^{-\alpha}t} X_s}{cX_{c^{-\alpha}t}} = \binom{\inf_{u \le t} cX_{c^{-\alpha}u}}{cX_{c^{-\alpha}t}}, \quad t \ge 0,$$

and the latter is equal in law to (X, \underline{X}) , because of the scaling property of X.

▶ Markov process $Z_t := X_t - (-x \land X_t), t \ge 0$ is also a ssMp on $[0, \infty)$ issued from x > 0 with index 2.

14/69

► $Z_t := X_t \mathbf{1}_{(\underline{X}_t > 0)}, t \ge 0$ is also a ssMp, again on $[0, \infty)$.

Some of your best friends are $\ensuremath{\mathsf{ssMp}}$

Suppose that $(X_t : t \ge 0)$ is an \mathbb{R}^d -Brownian motion:

- Consider $Z_t := |X_t|$, $t \ge 0$. Because of rotational invariance, it is a Markov process.
- Again the self-similarity (index 2) of Brownian motion, transfers to the case of |X|. Note again, this is a ssMp on [0,∞).

15/69

・ロト・日本・モト・モト・モー のへぐ

Some of your best friends are $\ensuremath{\mathsf{ssMp}}$

Suppose that $(X_t : t \ge 0)$ is an \mathbb{R}^d -Brownian motion:

- Consider $Z_t := |X_t|$, $t \ge 0$. Because of rotational invariance, it is a Markov process.
- Again the self-similarity (index 2) of Brownian motion, transfers to the case of |X|. Note again, this is a ssMp on [0,∞).
- ▶ Note that $|X_t|$, $t \ge 0$ is a Bessel-*d* process. It turns out that all Bessel processes, *and* all squared Bessel processes are self-similar on $[0, \infty)$. Once can check this by e.g. considering scaling properties of their transition semi-groups.

Suppose that $(X_t : t \ge 0)$ is an \mathbb{R}^d -Brownian motion:

Note when d = 3, $|X_t|$, $t \ge 0$ is also equal in law to a Brownian motion conditioned to stay positive: i.e if we define, for a 1-*d* Brownian motion ($B_t : t \ge 0$),

$$\mathbb{P}_{x}^{\uparrow}(A) = \lim_{s \to \infty} \mathbb{P}_{x}(A | \underline{B}_{t+s} > 0) = \mathbb{E}_{x} \left[\frac{B_{t}}{x} \mathbf{1}_{(\underline{B}_{t} > 0)} \mathbf{1}_{(A)} \right]$$

where $A \in \sigma\{B_t : u \leq t\}$, then

 $(|X_t|, t \ge 0)$ with $|X_0| = x$ is equal in law to $(B, \mathbb{P}^{\uparrow}_x)$.

LAMPERTI TRANSFORM FOR POSITIVE ssMp

Theorem (Part (i))

Fix $\alpha > 0$. If Z, is a positive self-similar Markov process issued from x > 0 with index of self-similarity α , then up to absorption at the origin, it can be represented as follows:

$$Z_t = \exp\{\xi_{\varphi(t)}\}, \qquad 0 \le t \le \zeta := \inf\{t > 0 : Z_t = 0\},$$

where either

- (1) $\zeta = \infty$ almost surely for all x > 0, in which case ξ is a Lévy process issued from log x satisfying $\limsup_{t \uparrow \infty} \xi_t = \infty$,
- (2) $\zeta < \infty$ and $Z_{\zeta-} = 0$ almost surely for all x > 0, in which case ξ is a Lévy process issued from $\log x$ satisfying $\lim_{t\uparrow\infty} \xi_t = -\infty$, or
- (3) ζ < ∞ and Z_{ζ−} > 0 almost surely for all x > 0, in which case ξ is a Lévy process issued from log x killed at an independent and exponentially distributed random time.

27/69

In all cases, we may identify $\zeta = I_{\infty}$.

LAMPERTI TRANSFORM FOR POSITIVE ssMp

Theorem (Part (ii))

Conversely, suppose that ξ is a given (killed) Lévy process issued from $\log x$, where x > 0. Define

$$Z_t = \exp\{\xi_{\varphi(t)}\}\mathbf{1}_{(t < I_\infty)}, \qquad t \ge 0.$$

Then Z defines a positive self-similar Markov process issued from x > 0, up to its absorption time $\zeta = I_{\infty}$, with index α .

where $\tau = \varphi(x^{-\alpha}t)$ is a stopping time in the natural filtration of ξ^* .

Noting that $\Psi^*(-i\alpha\hat{\rho}) = 0$, the change of measure constitutes an Esscher transform at the level of ξ^* .

Theorem

The underlying Lévy process, ξ^{\uparrow} , that appears through the Lamperti transform applied to $(X, \mathbb{P}_x^{\uparrow}), x > 0$, has characteristic exponent given by

$$\Psi^{\uparrow}(z) = \frac{\Gamma(\alpha \rho - \mathrm{i}z)}{\Gamma(-\mathrm{i}z)} \frac{\Gamma(1 + \alpha \hat{\rho} + \mathrm{i}z)}{\Gamma(1 + \mathrm{i}z)}, \qquad z \in \mathbb{R}.$$

► In particular $\Psi^{\uparrow}(z) = \Psi^*(z - i\alpha\hat{\rho}), z \in \mathbb{R}$ so that $\Psi^{\uparrow}(0) = 0$ (i.e. no killing!)

• One can also check by hand that $\Psi^{\uparrow\prime}(0+) = \mathbf{E}_0[\xi_1^{\uparrow}] > 0$ so that $\lim_{t\to\infty} \xi_t^{\uparrow} = \infty$.

- In essence, the case of the stable process conditioned to stay positive boils down to an Esscher transform in the underlying (Lamperti-transformed) Lévy process.
- It was important that we identified a root of $\Psi^*(z) = 0$ in order to avoid involving a 'time component' of the Esscher transform.
- However, there is another root of the equation

$$\Psi^*(z) = \frac{\Gamma(\alpha - iz)}{\Gamma(\alpha \hat{\rho} - iz)} \frac{\Gamma(1 + iz)}{\Gamma(1 - \alpha \hat{\rho} + iz)} = 0,$$

namely $z = -i(1 - \alpha \hat{\rho})$.

§1.	§2.	§3.	§4.	§5.	§6.	Exercises.
000000	0000000000000	0000	00000000000000	00000	00000000000000	000

▶ The three examples of pssMp offer quite striking underlying Lévy processes

40/69

(ロト・日本・日本・日本・日本・日本・1000)

Is this exceptional?

CENSORED STABLE PROCESSES

- Start with *X*, the stable process.
- Let $A_t = \int_0^t \mathbf{1}_{(X_t > 0)} dt$.
- Let γ be the right-inverse of A, and put $\check{Z}_t := X_{\gamma(t)}$.
- Finally, make zero an absorbing state: $Z_t = \check{Z}_t \mathbf{1}_{(t < T_0)}$ where

$$T_0 = \inf\{t > 0 : X_t = 0\}.$$

41/69

・ロト・日本・モト・モト・モー のへぐ

Note $T_0 < \infty$ a.s. if and only if $\alpha \in (1, 2)$ and otherwise $T_0 = \infty$ a.s. This is the censored stable process.

CENSORED STABLE PROCESSES

Theorem

Suppose that the underlying Lévy process for the censored stable process is denoted by $\tilde{\xi}$. Then $\tilde{\xi}$ is equal in law to $\xi^{**} \oplus \xi^{C}$, with

- \triangleright ξ^{**} equal in law to ξ^* with the killing removed,
- ► ξ^{C} a compound Poisson process with jump rate $q^{*} = \Gamma(\alpha) \sin(\pi \alpha \hat{\rho})/\pi$.

Moreover, the characteristic exponent of $\widetilde{\xi}$ is given by

$$\widetilde{\Psi}(z) = \frac{\Gamma(\alpha \rho - \mathrm{i}z)}{\Gamma(-\mathrm{i}z)} \frac{\Gamma(1 - \alpha \rho + \mathrm{i}z)}{\Gamma(1 - \alpha + \mathrm{i}z)}, \qquad z \in \mathbb{R}$$

42/69

THE RADIAL PART OF A STABLE PROCESS

- Suppose that X is a symmetric stable process, i.e $\rho = 1/2$.
- We know that |X| is a pssMp.

Theorem

Suppose that the underlying Lévy process for |X| is written ξ , then it characteristic exponent is given by

$$\Psi(z) = 2^{\alpha} \frac{\Gamma(\frac{1}{2}(-iz+\alpha))}{\Gamma(-\frac{1}{2}iz)} \frac{\Gamma(\frac{1}{2}(iz+1))}{\Gamma(\frac{1}{2}(iz+1-\alpha))}, \qquad z \in \mathbb{R}$$

HYPERGEOMETRIC LÉVY PROCESSES (REMINDER)

Definition (and Theorem) For $(\beta, \gamma, \hat{\beta}, \hat{\gamma})$ in

$$\left\{ \begin{array}{l} \beta \leq 2, \ \gamma, \hat{\gamma} \in (0,1) \ \hat{\beta} \geq -1, \ \text{and} \ 1 - \beta + \hat{\beta} + \gamma \wedge \hat{\gamma} \geq 0 \end{array} \right\}$$

there exists a (killed) Lévy process, henceforth refered to as a hypergeometric Lévy process, having the characteristic function

$$\Psi(z) = \frac{\Gamma(1 - \beta + \gamma - \mathrm{i}z)}{\Gamma(1 - \beta - \mathrm{i}z)} \frac{\Gamma(\hat{\beta} + \hat{\gamma} + \mathrm{i}z)}{\Gamma(\hat{\beta} + \mathrm{i}z)} \qquad z \in \mathbb{R}$$

The Lévy measure of Y has a density with respect to Lebesgue measure is given by

$$\pi(x) = \begin{cases} -\frac{\Gamma(\eta)}{\Gamma(\eta - \hat{\gamma})\Gamma(-\gamma)} e^{-(1-\beta+\gamma)x} {}_2F_1\left(1 + \gamma, \eta; \eta - \hat{\gamma}; e^{-x}\right), & \text{if } x > 0, \\ \\ -\frac{\Gamma(\eta)}{\Gamma(\eta - \gamma)\Gamma(-\hat{\gamma})} e^{(\hat{\beta} + \hat{\gamma})x} {}_2F_1\left(1 + \hat{\gamma}, \eta; \eta - \gamma; e^x\right), & \text{if } x < 0, \end{cases}$$

where $\eta := 1 - \beta + \gamma + \hat{\beta} + \hat{\gamma}$, for |z| < 1, ${}_2F_1(a, b; c; z) := \sum_{k \ge 0} \frac{(a)_k(b)_k}{(c)_k k!} z^k$.

Theorem

Suppose that $(\xi, \mathbf{P}_x), x \in \mathbb{R}$ is the Lévy process (not a compound Poisson process) underlying the pssMp $(Z, \mathbb{P}_x), x > 0$. The limit $\mathbb{P}_0 := \lim_{x \to 0} \mathbb{P}_x$ exists in the sense of convergence with respect to the Skorokhod topology if and only if $\mathbf{E}_0(H_1^+) < \infty$ (H^+ is the ascending ladder process of ξ). Under the assumption that $\mathbb{E}(\xi_1) > 0$, for any positive measurable function f and t > 0,

$$\mathbb{E}_0(f(Z_t)) = \frac{1}{-\alpha \hat{\mathbf{E}}_0(\xi_1)} \hat{\mathbf{E}}_0\left(\frac{1}{I_\infty} f\left(\left(\frac{t}{I_\infty}\right)^{1/\alpha}\right)\right),$$

where $I_{\infty} = \int_0^{\infty} e^{\alpha \xi_t} dt$ and $(\xi, \hat{\mathbf{P}}_0)$ is equal in law to $(-\xi, \mathbf{P}_0)$.

- This necessitated an incursion into the theory of Lévy processes
- ▶ What can we say about ℝ-valued self-similar Markov processes.
- ▶ This requires an incursion into the theory of Markov Additive (Lévy) Processes

MARKOV ADDITIVE PROCESSES (MAPS)

- *E* is a finite state space
- ▶ $(J(t))_{t>0}$ is a continuous-time, irreducible Markov chain on *E*
- ▶ process (ξ , J) in $\mathbb{R} \times E$ is called a *Markov additive process* (*MAP*) with probabilities $\mathbf{P}_{x,i}, x \in \mathbb{R}, i \in E$, if, for any $i \in E, s, t \ge 0$: Given {J(t) = i}, $(\xi(t+s) \xi(t), J(t+s)) \stackrel{d}{=} (\xi(s), J(s))$ with law $\mathbf{P}_{0,i}$.

53/69

PATHWISE DESCRIPTION OF A MAP

The pair (ξ, J) is a Markov additive process if and only if, for each $i, j \in E$,

- ▶ there exist a sequence of iid Lévy processes $(\xi_i^n)_{n>0}$
- ▶ and a sequence of iid random variables $(U_{ii}^n)_{n\geq 0}$, independent of the chain *J*,
- such that if $T_0 = 0$ and $(T_n)_{n \ge 1}$ are the jump times of *J*, the process ξ has the representation

$$\xi(t) = \mathbf{1}_{(n>0)}(\xi(T_n) + U_{J(T_n-),J(T_n)}^n) + \xi_{J(T_n)}^n(t-T_n),$$

54/69

イロト 不得 トイヨト イヨト 三日

for $t \in [T_n, T_{n+1}), n \ge 0$.

CHARACTERISTICS OF A MAP

- ▶ Denote the transition rate matrix of the chain *J* by $\mathbf{Q} = (q_{ij})_{i,j \in E}$.
- For each *i* ∈ *E*, the Laplace exponent of the Lévy process ξ_i will be written ψ_i (when it exists).
- ▶ For each pair of $i, j \in E$ with $i \neq j$, define the Laplace transform $G_{ij}(z) = \mathbb{E}(e^{zU_{ij}})$ of the jump distribution U_{ij} (when it exists).
- Otherwise define $U_{i,i} \equiv 0$, for each $i \in E$.
- Write G(z) for the $N \times N$ matrix whose (i, j)th element is $G_{ij}(z)$.
- Let

 $\Psi(z) = \operatorname{diag}(\psi_1(z), \ldots, \psi_N(z)) + \mathbf{Q} \circ G(z),$

(when it exists), where o indicates elementwise multiplication.

• The matrix exponent of the MAP (ξ, J) is given by

$$\mathbf{E}_{0,i}(e^{z\xi(t)}; J(t) = j) = \left(e^{\Psi(z)t}\right)_{i,j}, \qquad i, j \in E,$$

(when it exists).

DUAL MAP

- Thanks to irreducibility, the Markov chain *J* necessarily has a stationary distribution. We denote it by the vector $\boldsymbol{\pi} = (\pi_1, \dots, \pi_N)$.
- Each MAP has a dual process, also a MAP, with probabilities $\hat{\mathbf{P}}_{x,i}$, $x \in \mathbb{R}$, $i \in E$, determined by the dual characteristic matrix exponent (when it exists),

$$\hat{\boldsymbol{\Psi}}(z) := ext{diag}ig(-\Psi_1(-z),\cdots,-\Psi_N(-z)ig) + \hat{\boldsymbol{Q}}\circ \boldsymbol{G}(-z)^{\mathrm{T}},$$

where \hat{Q} is the time-reversed Markov chain *J*,

$$\hat{q}_{i,j} = \frac{\pi_j}{\pi_i} q_{j,i}, \qquad i,j \in E.$$

Note that the latter can also be written $\hat{Q} = \Delta_{\pi}^{-1} Q^{T} \Delta_{\pi}$, where $\Delta_{\pi} = \text{diag}(\pi)$. \blacktriangleright When it exists,

$$\hat{\boldsymbol{\Psi}}(z) = \boldsymbol{\Delta}_{\pi}^{-1} \boldsymbol{\Psi}(-z)^{\mathrm{T}} \boldsymbol{\Delta}_{\pi},$$

showing that

$$\pi_i \hat{\mathbf{E}}_{0,i} \left[e^{i z \xi_t}, J_t = j \right] = \pi_j \mathbf{E}_{0,j} \left[e^{-i z \xi_t}, J_t = i \right].$$

Lemma

The time-reversed process $((\xi_{(t-s)-} - \xi_t, J_{(t-s)-}), s \leq t)$ under $\mathbf{P}_{0,\pi}$ is equal in law to $((\xi_s, J_s), s \leq t)$ under $\hat{\mathbf{P}}_{0,\pi}$.

Theorem

Assume that Z is a conservative real self-similar Markov process. Moreover, suppose that the MAP $((\xi, \Theta), \mathbf{P})$, associated with Z through the Lamperti-Kiu transform, is such that ξ is not concentrated on a lattice and its ascending ladder height process H which satisfies $\mathbf{E}_{0,\pi}(H_1) < \infty$. Then $\mathbb{P}_0 := \lim_{x\downarrow 0} \mathbb{P}_x$ exists, in the sense of convergence of on the Skorokhod space, under which Z leaves the origin continuously. Conversely, if $\mathbf{E}_{0,\pi}(H_1) = \infty$, then this limit does not exist. Under the additional assumption that $\mathbf{E}_{0,\pi}(\xi_1) > 0$, for any positive measurable function f and t > 0,

$$\mathbb{E}_{0}(f(Z_{t})) = \frac{1}{-\alpha \hat{\mathbf{E}}_{0,\pi}(\xi_{1})} \sum_{i=\pm 1} \pi_{i} \hat{\mathbf{E}}_{0,i} \left(\frac{1}{I_{\infty}} f\left(i \left(\frac{t}{I_{\infty}} \right)^{1/\alpha} \right) \right), \tag{3}$$

where $I_{\infty} = \int_0^{\infty} \exp\{\alpha \xi_s\} ds$, and $\hat{\mathbf{E}}_{x,i}$, $x \in \mathbb{R}$, $i = \pm 1$.

ESSCHER TRANSFORM FOR MAPS

- If $\Psi(z)$ is well defined then it has a real simple eigenvalue $\chi(z)$, which is larger than the real part of all its other eigenvalues.
- Furthermore, the corresponding right-eigenvector $\mathbf{v}(z) = (v_1(z), \dots, v_N(z))$ has strictly positive entries and may be normalised such that $\pi \cdot \mathbf{v}(z) = 1$.

Theorem

Let $\mathcal{G}_t = \sigma\{(\xi(s), J(s)) : s \le t\}, t \ge 0$, and

$$M_t := \mathrm{e}^{\gamma \xi(t) - \chi(\gamma)t} \frac{v_{J(t)}(\gamma)}{v_i(\gamma)}, \qquad t \ge 0,$$

for some $\gamma \in \mathbb{R}$ such that $\chi(\gamma)$ is defined. Then, M_t , $t \ge 0$, is a unit-mean martingale. Moreover, under the change of measure

$$\left. \mathrm{d} \mathbf{P}_{0,i}^{\gamma} \right|_{\mathcal{G}_t} = M_t \left. \mathrm{d} \mathbf{P}_{0,i} \right|_{\mathcal{G}_t}, \qquad t \ge 0,$$

the process (ξ, J) remains in the class of MAPs with new exponent given by

$$\Psi_{\gamma}(z) = \Delta_{v}(\gamma)^{-1}\Psi(z+\gamma)\Delta_{v}(\gamma) - \chi(\gamma)\mathbf{I}.$$

Here, **I** *is the identity matrix and* $\Delta_{v}(\gamma) = \text{diag}(v(\gamma))$ *.*

Riesz-Bogdan-Zak transform

Theorem (Riesz–Bogdan–Zak transform)

Suppose that X is an α -stable process as outlined in the introduction. Define

$$\eta(t) = \inf\{s > 0 : \int_0^s |X_u|^{-2\alpha} du > t\}, \quad t \ge 0.$$

Then, for all $x \in \mathbb{R} \setminus \{0\}$, $(-1/X_{\eta(t)})_{t \ge 0}$ under \mathbb{P}_x is equal in law to $(X, \mathbb{P}^{\circ}_{-1/x})$, where

$$\frac{\mathrm{d}\mathbb{P}_{x}^{\circ}}{\mathrm{d}\mathbb{P}_{x}}\Big|_{\mathcal{F}_{t}} = \left(\frac{\sin(\pi\alpha\rho) + \sin(\pi\alpha\hat{\rho}) - (\sin(\pi\alpha\rho) - \sin(\pi\alpha\hat{\rho}))\mathrm{sgn}(X_{t})}{\sin(\pi\alpha\rho) + \sin(\pi\alpha\hat{\rho}) - (\sin(\pi\alpha\rho) - \sin(\pi\alpha\hat{\rho}))\mathrm{sgn}(x)}\right) \left|\frac{X_{t}}{x}\right|^{\alpha-1} \mathbf{1}_{\{t < \tau^{\{0\}}\}}$$

and $\mathcal{F}_t := \sigma(X_s : s \le t), t \ge 0$. Moreover, the process $(X, \mathbb{P}_x^\circ), x \in \mathbb{R} \setminus \{0\}$ is a self-similar Markov process with underlying MAP via the Lamperti-Kiu transform given by $\Psi^\circ(z)$.

EXERCISES

- 1. Suppose that *X* is a stable process in any dimension (including the case of a Brownian motion). Show that |*X*| is a positive self-similar Markov process.
- 2. Suppose that *B* is a one-dimensional Brownian motion. Prove that

$$\frac{B_t}{x} \mathbf{1}_{(\underline{B}_t > 0)}, \qquad t \ge 0,$$

is a martingale, where $\underline{B}_t = \inf_{s \le t} B_s$.

- 3. Suppose that *X* is a stable process with two-sided jumps
 - Show that the range of the ascending ladder process H, say range(H) has the property that it is equal in law to c × range(H).
 - Hence show that, up to a multiplicative constant, the Laplace exponent of *H* satisfies $k(\lambda) = \lambda^{\alpha_1}$ for $\alpha_1 \in (0, 1)$ (and hence the ascending ladder height process is a stable subordinator).
 - Use the fact that, up to a multiplicative constant

$$\Psi(z) = |\theta|^{\alpha} (\mathrm{e}^{\pi \mathrm{i} \alpha (\frac{1}{2} - \rho)} \mathbf{1}_{(\theta > 0)} + \mathrm{e}^{-\pi \mathrm{i} \alpha (\frac{1}{2} - \rho)} \mathbf{1}_{(\theta < 0)}) = \hat{\kappa}(\mathrm{i} z) \kappa(-\mathrm{i} z)$$

to deduce that

$$\kappa(\theta) = \theta^{\alpha \rho} \text{ and } \hat{\kappa}(\theta) = \theta^{\alpha \hat{\rho}}.$$

and that $0 < \alpha \rho, \alpha \hat{\rho} < 1$

What kind of process corresponds to the case that $\alpha \rho = 1$?

§1.	§2.	§3.	§4.	§5.	§6.	Exercises.
