1. Hash value
2. Alice has £29
3. Bob has £39
4. Charlie...
- 5....

CONSENSUS

- All members:**
- a) verify transactions
 - b) form consensus
 - c) confirm new block

1. Hash value
2. Alice has £19
3. Bob has £47
4. Charlie..
- 5....

1. Hash value
2. Alice has £29
3. Bob has £39
4. Charlie...
- 5....

Ways to get a consensus

Appoint a "leader"

Central authority ("permissioned")

- Fast
- Accurate
- Reliable
- Requires trust
- Subject to legal control

Hybrid or hierarchic

Bottom up pairwise

- Potentially very fast
- No formal proof yet

Run a "competition"

E.g. Bitcoin

- 1) "Miners" race to solve a computer problem.
- 2) Winner adds the new block

- Slow and Inefficient
- Security flaws
- No central authority !

- This is the key issue for a distributed, asynchronous system
- Systems that are reliable tend to be slow (1 TPS on average)
- Distribution introduces new security flaws

“Smart-contracts” - automatic matching and execution of contracts

SmartBlocks

Dashboard Search Contracts Account

Search

Search Offers Advanced Mode

[SWITCH TO SIMPLE MODE](#)

Asset name

Completion condition

Keywords: **AND OR**
Operations: <, >, =
Variables: price, quantity
Use parentheses to group statements.

Example:
(price < 100 AND (quantity > 20 AND quantity < 50))
OR (price < 120 AND quantity < 20)

Contract type

Buy

[SEARCH](#)

Keywords: **AND, OR.**

Operations: <, >, =

Variables: price, quantity

Use parentheses to group statements.

Example:

(price < 100 AND (quantity > 20 AND quantity < 50))

OR (price < 120 AND quantity < 20)

Price < 100

Price < 100 AND Quantity < 40

Expr AND ((Expr) OR Expr)

[pq][<=>][\d] + ([.][\d]+)?

Outline process:

- 1) Create offers to sell
- 2) Create requests to buy
- 3) Consensus shares offers
- 4) Match offers / requests
- 5) Propose “deals”
- 6) Consensus finalizes contracts

What works and what doesn't ?

Smart-contracts

- Smart-languages
- Low interoperability
- Language restrictions
- Cheap(ish)

Etherium,
HyperLedger
Ripple or hybrid

- 1) Events and triggers
- 2) Trade matching
- 3) Contract signing and encryption

Open, Distributed systems

Uses distributed processing to increase speed and security

Uses consensus process to support optimisation

Runs multiple smart-contract languages.

S
m
a
r
t
e
r

Traditional

- High speed (1000 TPS)
- High security - understood
- Expensive, centralized

IBM / Oracle /
MySQL

- 1) Data management
- 2) Events and triggers
- 3) Signing and encryption

Open, distributed ("un-permissioned") Blockchain

- Slow (1TPS) and Long latency (5-10 minutes)
- Security and reliability risks
- Pseudo-anonymous
- No central control (no legal authority)

Bitcoin, XXXcoin

- 1) Crypto-currency transactions
- 2) Exchange of value

More distributed

Central or distributed?

Permissioned or open?

How does the consensus work?

How fast is it?

How secure is it?
