(University of Warwick)

May 22, 2014

## Abstract

This paper investigates the effect of stolen goods markets on crime. We focus on *pawnshops*, a business that have long been suspected of illicit trade. The analysis of a unique panel dataset of 2176 US counties from 1997 - 2010 uncovers an elasticity of pawnshops to theft crimes of 0.8 to 1.4. We then exploit the raise in gold price as a quasi - natural experiment, where the intensity of the treatment is given by the predetermined concentration of pawnshops in the county. A one standard deviation increase in pawnshops' initial allocation raises the effect of gold price on burglaries by 0.05 to 0.10 standard deviation. No effect is ever detected on any other type of crime.

*“If he’s coming in my store with a VCR, I’m not asking him where he got it. It’s the police’s job to find out if it’s stolen, not mine. You don’t ask where things come from. If you don’t take those, the guy down the street will”* (Glover and Larubbia, 1996)

## 1 Introduction

Theft crimes produce a substantial harm to society. In 2010, United States have experienced 1 theft every 40.5 seconds, with an estimated total of 9.5 million crimes that caused an economic loss for the victims of almost \$16 billions (FBI, 2010).<sup>1</sup> In 85% of the cases something different from cash was stolen, strongly suggesting that burglars need a market where to convert stolen items into

<sup>1</sup>Personal calculation from the author, obtained summing up data on larceny, robbery, burglary and motor and vehicle theft from the FBI reports for the year 2010.

profits. In particular, the local availability of stolen goods markets might affect criminals' behavior through two different channels: 1) reducing theft - related transaction costs and hence lowering burglars' probability of arrest 2) increasing the price for the stolen property and - consequently - raising the expected benefits deriving from criminal activity. Nevertheless, despite the understanding of the link between demand and supply of crime seems to be of critical importance to reduce the proliferation of theft crimes, a systematic empirical investigation of the effect of stolen goods markets on criminal behavior is missing.<sup>2</sup> Two main obstacles hinder this type of analysis. First, markets for stolen properties are hardly identifiable. Secondly, these are not randomly assigned to geographic locations.

This paper investigates the effect of stolen goods markets on crime through the lens of *pawnshops*, a widespread legal business that have long been suspected of illicit trade. While the proponents of these business, led by the National Pawnbrokers Association, stigmatize the frequency of this phenomenon, public opinion, newspapers and criminologists point the finger against this "modern thief's automatic cash machine" (Glover and Larubbia, 1996).

Despite the different standpoints, obtaining evidence on the effect of potential stolen goods markets on the supply of crime is complicated by a number of reasons. Pawnshops mainly serve the credit needs of low income people. Hence, the endogenous sorting of pawnshops in communities with a large presence of potential customers biases upward ordinary least squares (OLS) estimates, given that these communities usually experience an higher level of crime. Further biases are caused by omitted variables that correlates with both the presence of pawnshops and crime, or by the possibility that the endogenous sorting of pawnshops is a direct response of the expected level of crime in the community (reverse causality bias).

We address these issues in several ways. In the first part of the paper, the empirical strategy relies on the properties of a unique panel dataset constructed for the analysis: 2176 counties in 50 states, almost 70% of the US total, from 1997 to 2010. The structure of the panel allows for the inclusion of county fixed effect, that control for unobserved time invariant heterogeneity across counties. The baseline empirical analysis focuses on the effect of the within county variation in the number of pawnshops on the number of reported theft crimes. Year fixed effects and states linear trends

---

<sup>2</sup>Different studies have analyzed a wide set of crime's potential determinants. Among these we find: the effect of police and incarceration (Levitt 1997, Di Tella and Schargrodsky 2004, Klick and Tabarrok 2005, Levitt 1996, Levitt 1998, Helland and Tabarrok 2007, Drago, Galbiati and Vertova 2009, Lee and McCrary 2009, Draca, Machin and Witt 2011), conditions in prisons (Katz, Levitt and Shustorovich 2003), parole and bail institutions (Kuziemko 2007), education (Western, Kling and Weiman 2001, Lochner and Moretti 2004), social interactions and peer effects (Case and Katz 1991, Glaeser, Sacerdote and Scheinkman 1996, Gaviria and Raphael 2001, Kling, Ludwig and Katz 2005, Jacob and Lefgren 2003, Bayer, Hjalmarsson and Pozen 2009), family circumstances (Glaeser and Sacerdote 1999, Donohue and Levitt 2001). Economists have also focused on the the effect of criminal histories on labor market outcomes (Grogger 1995, Kling 2006), the impact of unemployment and wages on crime (Grogger 1998, Raphael and Winter- Ebmer 2001), the strategic interplay between violent and property crime (Silverman 2004), the optimal law enforcement (Polinsky and Shavell 2000, Eeckhout, Persico and Todd 2009) the immigration status (Bianchi, Buonanno and Pinotti 2012) and the impact of violent movies and pornography on violent crimes (Dahl and Della Vigna 2009 and Bhuller, Havnes, Leuven and Mogstad 2011).

control for nationwide and state specific confounding shocks. Moreover, the analysis includes a rich set of county, time varying, socioeconomic controls such as: income per capita, percentage of people below the poverty line, unemployment, the number of social security recipients, the average monthly payment per subsidy, the number of commercial banks and saving institutions, the number of sworn police officers and civilian employees, the population density and the racial/ethnic composition in the county. Finally, to control for changes in drug penetration and risky behavior, we add data on arrests for sale and possession of drugs (opium/cocaine, marijuana, synthetic drugs and other dangerous non narcotics) and gambling (bookmaking horse and sports, numbers and lotteries and all other illegal gambling). The clear attempt is to shut down possible endogeneity concerns due to the omission of county specific time varying unobservables.

Results are startling. Ordinary least squares estimates show a strong effect of pawnshops only on two specific theft crimes: larceny and burglary, with an elasticity of 1.4 and 0.8. These findings are robust to extensive robustness checks, the clustering of standard errors at different levels, the sensitivity to outliers, weighting the regression by a measure of the quality of the information available to the researcher, using different functional forms and excluding from the sample counties with big population.

Moreover, implicit falsification tests on other crimes - that should not be directly affected by the presence of these businesses - disprove the possibility that pawnshops might influence crime through different channels other than the potential demand for stolen goods. In particular, the availability of data on motor - vehicle thefts gives the possibility of unambiguously testing the hypothesis of the paper. This particular theft crime is totally insensitive to the presence of pawnshops in the county, plausibly because motor and vehicles are never accepted in pawnshops' transactions. Furthermore, no effect is detected on any other crime.

The effect on larcenies and burglaries is more acute in densely populated counties, where - plausibly - the anonymity of the environment amplifies the likelihood of the pawnshop being a convenient destination for stolen items. In less densely populated areas instead, pawnshops might be far from the crime scene, crime is generally less frequent and residents are more willing to defend the interests of the members of their communities. This might discourage thieves to use this channel to get rid of stolen items.

We further extend the analysis in the attempt to detect geographical spillover effects on crime. We do so by constructing other two different measures of pawnshops' concentration 1) in bordering counties 2) and at the state level. Interestingly, results show that within county changes in larcenies and burglaries are significantly affected from the variation of the number of pawnshops in the same county but also in the same state. These results partly confirm the findings obtained from several burglars' interviews (Sutton, 2010). In fact, knowing that the probability of arrest increases while stolen property is in possession, burglars prefer to commit thefts at a maximum distance of half an hour by car from the predetermined resale point (Sutton, 2010). On the other hand, we also find

evidence that burglars might take the risk of traveling far from the crime scene, plausibly to avoid suspects about the origin of the item or to outdistance the good from the place where it was stolen.

Despite the use of panel data techniques, the lack of random assignment of pawnshops to counties poses two different threats to the identification of a causal parameter. First of all, results might be driven by the omission of time variant unobservables both related to within county changes in the number of pawnshops and theft crimes. But, what magnitude should have the bias to completely invalidate our findings? The Altonji et al. (2005) method of assessing selection on unobservables using selection on observables is pursued in this context. The rule of thumb outlined in Nunn and Wantchekon (2012) is that any ratio above 1 is acceptable. In our case the Altonji ratio is above 10 for theft crimes, finally suggesting that there is little concern that selection on unobservables is the main driver of our results.

A second econometric concern is related to the bias arising from the reverse causality between pawnshops and larcenies/burglaries. Despite the interesting implication related to the positive sorting of pawnshops in counties with a high level of theft crimes, (conditional on all the covariates included in the dataset), we totally overcome this issue in the last section of the paper, by introducing in the analysis the price of gold.

Gold has always been the major determinant of pawnbrokers' profit function, roughly representing 80 percent of the value of all pledges (Bos et al, 2012). Pawnbrokers' demand for gold materializes through the request of jewelry. But, what makes jewelry and - in particular - gold so profitable for pawnbrokers' activities? A big part of the pawnbrokers' profits comes from the process of melting down the gold received by their clients through the "refinement" process. In fact, 90% of the times pawnbrokers sell their jewelry to a company that is known as a 'refiner.' A refiner will take all of the rings, necklaces, bracelets and other items and melt them. Truly professional outfits will then begin to remove impurities from the metals until they get something close to pure gold. Hence, stolen jewelries might disappear forever from the second - hand market when they are transformed into a bar of precious metal.

This persistent demand for jewelry and gold in particular might influence criminal behavior. In fact, as in any other type of economic activity, the exact knowledge of the demand for stolen goods might affect the type of items that are actually stolen. The underlying hypothesis of the paper is that the shift in the resale value of gold, exogenously determined by changes in the macroeconomic conditions, while potentially increasing burglars' expected benefits of committing a theft uniformly in all counties, might cause relatively more theft crimes in counties with a higher predetermined concentration of markets interested in acquiring gold. In practice, we further address the endogeneity of pawnshops to crime exploiting the exogenous rise in the price of gold as a quasi - natural experiment, where the intensity of the treatment is given by the concentration of pawnshops in the county fixed to the first year of the sample.

Again, results strongly support our hypothesis. A one standard deviation increase in the initial

concentration of pawnshops in the county increases the effect of the rise of gold price on burglaries by 0.05 to 0.10 standard deviation. Conversely, the effect on larceny, that usually includes thefts of bicycles, motor vehicle parts and accessories, shoplifting, pocket-picking, or the stealing of any property or article that is not taken by force, is noisy and not precisely estimated. As in the first part of the paper, no effect is detected on motor and vehicle thefts and on all other crimes. As a further falsification test, we repeat the same exercise including the interaction between the initial concentration of pawnshops and the price of copper. Reassuringly, we do not detect any positive effect on burglaries. In fact, objects containing copper, while being heavily targeted by criminals, are usually not accepted in pawnshops' transactions.

This paper has the power to inform policy. A closer monitoring of pawnshops from local authorities, (as well as of other potential markets for crime not considered in this paper), in fact seems to be warranted. This improved monitoring could plausibly reduce the illegal demand for stolen goods and, consequently, the number of theft crimes in pawnshops' surrounding area.

To conclude, we believe that the main and most relevant contribution of this paper is a first step towards a systematic empirical investigation of the link between demand and supply of crime, an extremely important issue never properly explored in the existing literature on the determinants of crime.

This paper proceeds as follows. Section 2 presents some suggestive evidence related to the link between pawnshops and theft crimes. Section 3 presents the data and lays down the initial econometric framework, reporting the different results, various robustness checks and heterogeneity in the results. Section 4 introduces the role of gold in the quasi natural experiment, outlines the research design and presents the results. Section 5 concludes the paper.

## 2 Pawnshops As a Market Place for Stolen Goods: Suggestive Evidence

Pawnshops, payday loans and check cashing outlets are all businesses that provide credit to "unbanked" clients at a very high interest rates.<sup>3</sup> Nevertheless, within all these activities, pawnbrokers offer a unique service: the supply of instant cash to their clients, only through the exchange of personal property's items. The standard procedure begins with the assessment of the monetary value of the item brought by the client. If the client agrees with the offer received, she can either directly sell the item to the pawnbroker or she can ask for a loan, using the pledge as a collateral.

---

<sup>3</sup>U.S. households purchased more than \$40 billion in high-cost short-term loans using the "fringe banking sector" in 2007, Fellowes and Mabanta (2008). Even if there is no official and reliable estimate of the total number of clients, industry reports suggest that 34 million adults demanded the services of these companies. The sector consists of several types of high-cost lenders, but two comprise the dominant portion: payday lenders and pawnshops. In 2007 pawnshops made 42 million transactions for an overall value of 2.5 billion dollars. The maximum interest rate set by pawnbrokers and payday lenders is generally regulated at the state level. For a complete review of pawnshops' operating system see Shackman and Tenney (2006).

Usually, the offer ranges from 30 to 75 per cent of the market value of the pledge, with the average loan value being 100\$ for a two months period. The pawnbroker holds the personal item in custody until the maturity date of the loan. In case the client does not return to claim back the pledged item at the maturity date, this becomes pawnbroker's property.<sup>4</sup>

Given that pawnbrokers assume the risk that an item might have been stolen, laws in many jurisdictions protect the brokers from unknowingly handling stolen goods.<sup>5</sup> These laws usually require, for each transaction, a photo identification of the client (such as a driver's license or government-issued identity document), as well as a "holding" period on the item purchased by the pawnbroker, to allow local law enforcement authorities to track stolen items. For the same reason, pawnshops must regularly communicate to police a list of all newly pawned items and, if possible, any associated serial number. Nevertheless, to be found guilty of criminal possession, the pawnbroker must know that the item he is accepting is actually stolen, a fact often difficult to prove. Consequently, the main risk that the pawnbroker faces is the loss of both the collateral and the amount loaned, if the police seize the item.

According the National Pawnbrokers Association (NPA), the best way to avoid the unknowingly handling of stolen goods is "...*(by) refusing any items that are suspicious in nature or thought to be misappropriated*". Nevertheless, "... *less than half of one per cent of all pawned merchandise is identified as stolen. That's because customers must provide positive identification and a complete description of the merchandise. This information is then regularly transmitted to law enforcement, which dramatically decreases the likelihood that a thief would bring stolen merchandise to a pawn store*". The NPA claim is supported by some industry study. In an inspection of 65,000 pawn transactions made in Dallas County, only 0.4 per cent of the items were identified as stolen (Scott 1992). Similar results are reported for Oklahoma (Wheat 1998) and in Florida for Collier and Palm Beach counties (Florida Committee on Criminal Justice 2000).

Regardless of the existence of an accurate legislation, different dynamics can turn a pawnshop into a market for stolen goods (Sutton, 2010). First of all thieves, exploiting the increase in personal properties' trade in the community, can circumvent the security measures of an honest pawnbroker, "disguising" the stolen property in the regular flow of allowed items. Then, in some cases, the competition for profits could undermine pawnbrokers' security policy, leading him to accept - from time to time - items of uncertain origin. Finally, in a worst scenario, the pawnbroker could explicitly facilitate the sale of stolen goods in his shop (fencing), exploiting the lack of a strict law enforcement from local authorities or - for example - the fact that the majority of stolen goods lack of a unique identifier and are hardly recognizable by police or by the victims.<sup>6</sup>

---

<sup>4</sup>Alternatively, the pawnbroker becomes the owner of the item as soon as the sale process ends. Around 80 percent of pawn loans tend to be repaid and repeat customers account for much of the loan volume. Moreover, it is common for a customer to use the same pledge as collateral to obtain sequential loans (Avery, 2011).

<sup>5</sup>Data on state level laws from 1997 to 2010 are unavailable to the researcher

<sup>6</sup>Pawnbrokers have often been associated with fencing. While pawnbrokers do not like this characterization of their business, police efforts have indicated that some pawnbrokers are actually involved in fencing. For example, in

On this note some investigative reports - narrowly focusing on the criminal histories of the most frequent pawners - support the hypothesis that pawnshops deal with stolen property items. The first analysis of this type was conducted by Glover and Larrubia (1996). The reporters, after gathering all 70,000 pawn slips in Ft. Lauderdale, ranked pawnshops clients by the number of transactions made in that year. Thirty-nine of these top 50 pawners had criminal arrest records, nineteen of which were for burglary, theft, or related offenses.<sup>7</sup> Fass and Francis (2005) used a similar approach to analyze a database of all pawn transactions recorded by the Dallas Police Department (DPD) during the six-year period from January 1, 1991, through December 31, 1996.<sup>8</sup> The evidence from this analysis is startling. The 14,500 people pawning 30 times or more during the period were responsible of the 24 per cent of total loan value. These frequent pawners “... *were two to three times more likely to have been convicted for theft, larceny, burglary, or robbery than those who pawned once or twice*”. Moreover “... *nearly 65% of the 1,100 individuals within the group who pawned more than one hundred times had arrest records, more than half of them for some kind of stealing*”.<sup>9</sup>

Wright and Decker (1994) interviewing burglars in the St. Louis area, describe different mechanisms through which pawnshops may be used to quickly convert stolen goods into cash. First, even if the burglar must provide his name, address, and a form of identification, rarely jurisdictions make full use of this information. Moreover, these requirements can be easily deceived. The burglar may provide false information (Glover and Larrubia, 1996) or use false identification when needed. Alternatively, some burglars reported persuading friends to pawn the items for them, reducing the likelihood that the pawnbroker would not accept the item from a suspicious client (Wright and Decker, 1994). Finally, jewelry such as rings, bracelets and necklaces can be easily melted down, transforming forever stolen items into an unrecognizable bar of precious metal (Sutton, 2010). We will further discuss this point in the last section of the paper.

---

the US, the Sarasota Police Department, Venice Police Department and North Port Police Department assisted with the undercover operation to sell gold jewelry to each business. Many were found to be in compliance. However, a number of businesses were operating under a 'no questions asked' policy, making no attempt to properly document the seller information, record the items being purchased or obtain the seller's fingerprint, all of which are state requirements" (Bill, 2011)

<sup>7</sup>In a subsequent study Wallace (1997) describes how pawnshops may enable a few highly motivated criminals to commit many offenses. For example, an unemployed man visited a single pawnshop 38 times in less than two months and pawned, among other items, thirteen women's rings, ten men's rings, eleven necklaces, nine cameras, six watches, three VCRs, and two televisions. The day after his last visit to the pawnshop, the man was arrested for burglary. Another police survey of frequent pawners produced like findings in Portland, Oregon. 90 per cent of these pawners were chronic drug users with long criminal records (Hammond 1997).

<sup>8</sup>Each transaction shows a pawn ticket number, a pawner identification number, shop identification number, transaction date, and classification code for items pawned.

<sup>9</sup>Within the sample of the top 100 pawners, 83 individuals had arrest records. “*Of these, 58 had accumulated 300 convictions for property as well as other offenses, or an average of 5.2 arrests per individual. Most property crime arrests, 74 per cent, were for theft, 11 per cent for burglary of vehicles, 7 per cent for burglary of homes or businesses, 5 per cent for robbery, and the rest for forgery and car theft. Other infractions mainly involved drug possession (23 per cent) or driving without a license (23 per cent)*”. A similar analysis, conducted by Comeau and Klofas (2012) for the city of Rochester, NY shows equivalent evidence.

## 3 Data and Empirical Analysis

### 3.1 Data

This paper focuses on a strongly balanced panel of 2176 US Counties, (70% of all the counties in the United States), in 50 States from 1997 to 2010. The final dataset is obtained merging information from several sources. Data on crime is accessed through the National Archive of Criminal Justice Data.<sup>10</sup> Eight different type of crimes are reported: larceny, burglary, robbery, motor-vehicle theft, murder, aggravated assault, rape, arson.<sup>11</sup> Data on our variable of interest - the total number of pawnshops by county per year - is obtained by Infogroup Academic, a US private company.<sup>12</sup> Figure 3.1 shows the geographic distribution of the number of pawnshops in 1997, the first year in our analysis.<sup>13</sup>

Figure 3.1:

Table 1 reports crime - related summary statistics, expressed by county and normalized per 100,000 people. The average number of pawnshops is 5.88, with a standard deviation of 6.32.<sup>14</sup> Larceny is the most common theft crime, followed by burglary and motor - vehicle theft.<sup>15</sup> Violent crimes and arson are less frequent, with the lowest reported crime being murder, with an average of 3.89 and a standard deviation of 5.43.

Table 1:

---

<sup>10</sup>Data is freely downloadable at : [http://www.icpsr.umich.edu/icpsrweb/content/NACJD/guides/ucr.html#desc\\_cl](http://www.icpsr.umich.edu/icpsrweb/content/NACJD/guides/ucr.html#desc_cl).

<sup>11</sup>County-level files are created by NACJD based on agency records in a file obtained from the FBI that also provides aggregated county totals. NACJD imputes missing data and then aggregates the data to the county-level. The FBI definition of the eight types of crime can be found in the data appendix.

<sup>12</sup>More informations available at <http://lp.infogroup.com/academic>. Infogroup provided me with the overall number of pawnshops by county, per year. The data gathering process follows a six step procedure. In the compilation phase, data is taken directly from different sources such as: Government, public company filings, Utility Information, NCOA, Tourism Directories, web compilation and RSS Feeds etc... The second step in the process is the address standardization process followed by a phone verification phase with 40 millions call made per year. The last three phases include a standardization of elements and a duplicate removal, an enhanced content and a final quality check.

<sup>13</sup>In our sample of 70% of all the counties in the United States we have an average of 9800 pawnshops per year. These numbers are confirmed by other studies. See - for example - Fellowees and Mabanta (2008), Shackman and Tenney (2006).

<sup>14</sup>In our empirical framework we exploit the within county variation in the number of pawnshops that represents 54% of the sample mean.

<sup>15</sup>In the FBI's Uniform Crime Reporting (UCR) Program, property crime includes the offenses of burglary, larceny-theft, motor vehicle theft, and arson. The property crime category includes arson because the offense involves the destruction of property; however, arson victims may be subjected to force. Because of limited participation and varying collection procedures by local law enforcement agencies, only limited data are available for arson. In the FBI's Uniform Crime Reporting (UCR) Program, violent crime is composed of four offenses: murder and non negligent manslaughter, forcible rape, robbery, and aggravated assault. Violent crimes are defined in the UCR Program as those offenses which involve force or threat of force.

This study also uses a wide set of county - time varying - socioeconomic controls, obtained from the US Census Bureau.<sup>16</sup> Data on labour market is obtained from the Bureau of Labor Statistics-Current Population Survey while Data on the number of sworn police officers and civilian employees comes from the Department of Justice-Federal Bureau of Investigation.<sup>17</sup>

### 3.2 Empirical Analysis

We start the empirical analysis by estimating the following OLS equation:

$$y_{i,s,t} = \alpha_i + \gamma_t + \mu_{s,t} + X'_{i,s,t}\beta_0 + \#pawn_{i,s,t}\beta_1 + \epsilon_{i,s,t}$$

where  $i$  indicates the county,  $s$  the state and  $t$  the year. The outcome of interest is the number of reported crimes, by county per year. The coefficient of interest is  $\beta_1$ , the effect of pawnshops on crime. Both the number of crimes and the number of pawnshops are expressed in per capita terms. Standard errors are clustered at the county level, to allow for serial correlation of the error term within county.

The identification strategy heavily relies on the properties of the panel dataset. First, we exploit within county variation by including county fixed effects  $\alpha_i$ . In this way we control for the presence of time invariant unobserved characteristics that can be related to the evolution of pawnshops and crime. Then, we condition on year fixed effects  $\gamma_t$  and state linear trends  $\mu_{s,t}$  to control for nationwide and state specific confounding shocks.

Finally, we include  $X'_{i,s,t}$ , a vector of county time - varying socioeconomic controls. The clear attempt is to control, to the best of our possibilities, for the presence of confounding factors both related to the rise of pawnshops and crime in the county. We include income per capita, percentage of people below the poverty line, percentage of unemployment, the number of social security recipients and the average monthly payment per subsidy. Given the type of credit service provided by pawnshops, we add the number of commercial banks and saving institutions in the county. These controls, together with the amount of banking and saving deposits, aim to capture time varying confounding unobservables, both related to the financial penetration in the county and the relative presence of crime. We add the number of sworn police officers and civilian employees,<sup>18</sup> the population density and the racial/ethnic composition in the county, that implicitly controls for the presence of possible confounding migration patterns.<sup>19</sup> Finally, to control for the variation in drug penetra-

---

<sup>16</sup>The majority of information is gathered through the following web site: <http://censtats.census.gov/usa/usa.shtml>.

<sup>17</sup>Sworn police officers are law enforcement employees with arrest powers. Civilian employees include personnel employed by each local agency who do not have arrest powers and include job classifications such as clerks, radio dispatchers, meter maids, stenographers and accountants.

<sup>18</sup>We include sworn police officers and civilian employees at the state level in the year (t-1), due to some concern related to the possibility of controlling for a potential outcome.

<sup>19</sup>The racial origin is defined according to the following four categories: White, Black, Asian and Indian American. Moreover each race is divided in Hispanic or Not Hispanic ethnic origin.

tion and risky behavior, we add data on arrests for sale and possession of drugs (opium/cocaine, marijuana, synthetic drugs and other dangerous non narcotics) and gambling (bookmaking horse and sports, numbers and lotteries and all other illegal gambling). Table 2 reports the summary statistics of all the controls included in the analysis.

Table 2:

### 3.2.1 Results

Table 3 shows the evolution of  $\beta_1$  both for the aggregated measure of theft crimes (obtained by summing up larceny, burglary, robbery and motor vehicle theft) and for the other crimes (murder, aggravated assault, rape, arson). The general decreasing pattern of the coefficient of interest indicates the importance of adding fixed effects and all the described socioeconomic controls. Results from the two most complete specifications are shown in column 5 and 10, where we include all fixed effects and all controls.<sup>20</sup> For the case of theft crimes, we observe a positive coefficient of 6.07, significant at the 1% level, while no significant effect of pawnshops on other crimes is detected.

Table 3:

In table 4 we perform the same analysis for each type of crime. Interestingly, we detect a positive and significant effect only on larcenies and burglaries. The coefficient of pawnshops on larcenies is 4.57 and it is significant at the 1% level, while the coefficient on burglaries is 1.52 and it is significant at the 5% level. No effect is detected on robberies, motor - vehicle thefts and on all other crimes.

Table 4:

Table 5 shows the results when we use a log - log specification. Results do not depend on the functional form used. In fact, a one percent increase in the number of pawnshops per capita is related to a 1.5 and 0.8 percentage increase in the number for larcenies and burglaries, respectively.

Table 5:

### *Discussion of the Results*

The above results strengthen the hypothesis that pawnshops might influence theft crime through their potential demand for stolen goods. In fact, we observe a strong positive effect of the number of pawnshops *only* on larcenies and burglaries. Larceny is the most generic (and most frequent)

---

<sup>20</sup>Results are totally unchanged if we include state FE \* year FE instead of state linear trends.

type of theft. It includes shoplifting, pocket picking, purse snatching, theft of objects from motor vehicles, theft of bicycles and theft of items from buildings in which the offender has legal access. Burglaries instead, are essentially larcenies aggravated by the unlawful entry in a private property. These two types of crime seem to have in common a certain degree of premeditation that - plausibly - could be encouraged by the presence of pawnshops in the county.

Moreover, we implicitly test the validity of the mechanism analyzing the effect on crimes that are not supposed to be directly affected by the presence of pawnshops. The most meaningful falsification test is on motors and vehicles thefts, given that these vehicles are not usually accepted from pawnshops. Reassuringly, we do not detect any effect on this crime and on all the other crimes.

### ***Selection on Unobservables***

Given the lack of random assignment, we can not exclude that the omission of some time variant unobservables might be driving the results on larcenies and burglaries. But, how big should be this bias in order to completely invalidate our results? The Altonji et al. (2005) method of assessing selection on unobservables using selection on observables is pursued in this context. The intuition behind the test is to measure how strong the selection on unobservables must be relative to the selection on observables in order to explain away the effects. This strategy relies on a comparison between a regression run with potentially confounding factors controlled for, and one without.<sup>21</sup> The rule of thumb is that any ratio above 1 is acceptable, as it indicates that selection on unobservables must be larger than selection on observables in order to invalidate the results (Nunn and Wantchekon, 2012). In our specification, the Altonjii ratio is above 10 for theft crimes, finally suggesting that there is little concern that selection on unobservables is driving the results of the analysis.

### ***Reverse Causality***

Pawnbroker's choice of locating or opening the business in a particular county might depend on the previous level of burglaries and larcenies in the areas. In one extreme case, pawnbrokers might decide to avoid to locate their shop in counties with high level of these two theft crimes. If that were the case, our  $\beta_1$  coefficient would suffer - if anything - from a downward bias. In the opposite case, we could observe positive selection of in counties with an high level of larcenies and burglaries. This phenomenon, while potentially inflating the effect of pawnshops on crime and hence undermining the precision of our estimate, it would not make the analysis less interesting. In fact, what would be the logic of deliberately locating a pawnshop in a high crime community? Honest pawnbrokers would expect less honest customers, (ceteris paribus, relatively more potential clients would have been victim of a theft). Moreover, this particular choice might endanger the same pawnbroker,

---

<sup>21</sup>Let  $c$  denote the estimate with controls, and  $nc$  denote the estimate without controls. The Altonji ratio is  $|\frac{\beta_c}{\beta_{nc}-\beta_c}|$ .

increasing the likelihood of being a victim of a theft.<sup>22</sup> Table 6 further investigates this aspect focusing on the lagged effect of pawnshops’ concentration on larcenies and on burglaries.

Table 6:

In both cases the inclusion of pawnshops at  $t - 1$  and  $t - 2$  determines a loss of precision of the estimates. Nevertheless, the effect of the concentration on pawnshops at  $t - 2$  dominates the other effect for the case of burglaries and it also has a big magnitude for larcenies. Table 7 instead analyzes the concentration of pawnshops as a function of the contemporaneous and past levels of theft crimes.

Table 7:

Looking at column 3 and 6 we observe a more stable distribution of the effects when we include lagged variables up to two years before.

While this test does not represent an exhaustive scientific argument to support our hypothesis, it is important to notice that we will shut down the reverse causality circle in the second part of the paper, where we will focus on the effect on crime of the initial (and constant overtime) concentration of pawnshops in the county, interacted with the gold price.

### 3.3 Robustness Checks

Table 8 shows the set of robustness checks for larceny (Panel A) and burglary (Panel B).

Table 8:

Column 1 reports the coefficient when we cluster standard errors at the state level, while in column 2 we show the results with double clustering at county - year level (taking into account both autocorrelation of the error structure within county over time and the spatial correlation in each year across counties). In column 3 we weight the regression by the coverage indicator reported by the agency, a measure of the reliability of the information available to the researcher.<sup>23</sup> Finally,

---

<sup>22</sup>Another source of concern could be related by the “ad hoc” targeting of pawnshops from burglars. We tend to disprove this possibility for three reasons. First, there does not seem any evidence related to the possibility that pawnshops are a constant target from burglars, while a quick google search shows that pawnshops are usually associated to be a potential market for stolen goods. Second, this shops usually have an high level of security that should not allow clients to commit an harmless larceny in the shop. Third, 74% of the burglaries hit residence while only 26 affect stores (FBI, 2010).

<sup>23</sup>The Coverage Indicator variable represents the proportion of county data that is not imputed for a given year. The indicator ranges from 100, indicating that all ORIs in the county reported for 12 months in the year, to 0, indicating that all data in the county are based on estimates, not reported data. The Coverage Indicator is calculated as follows:  $CI_x = (1 - (sum((ORI_{ipop}/countypop)((12 - monthsreported/12)))) * 100$  where CI = Coverage Indicator, x = county, i = agency within county. We exclude from the analysis observations for which the coverage indicator equals 0.

we perform two tests to check the sensitivity to outliers. In column 4 we eliminate from the sample the counties in the top 1% of the pawnshops' per capita distribution. In column 5 we drop from the sample of the analysis the counties in the top 1% of the population distribution.<sup>24</sup> The stability of the coefficient is shown across all different specifications.

### 3.4 Heterogeneity in the Results

#### 3.4.1 Population Density

The anonymity and the dispersion of a big city might amplify the likelihood of the pawnshop being a convenient destination for stolen goods. In rural and less densely populated areas instead, the pawnshop might be far from the crime scene. Moreover, in these areas criminal activity is generally less frequent, and residents are more willing to defend the interests of the members of their communities. All these considerations could undermine the burglars' incentives of trying to use the local pawnshop to sell stolen goods (and hence to commit a burglary in its proximity). For this reason, we investigate for the possible presence of an heterogeneous effect, dividing the sample in "low" and "high" population density counties. The two categories are computed with respect to the median density in the sample.

Table 9 shows results in line with the hypothesis that population density can be an important factor that amplifies the effect of pawnshops on theft crimes. For the case of larceny, the coefficient is 10.4 and it is significant at the 1% level in high densely populated counties, while it is 3.36 significant at the 10% in low density counties. The same pattern can be found for burglaries.

Table 9:

#### 3.4.2 Geographical Spillovers

The empirical analysis has been focused so far on understanding the effect of the within county change in the number of pawnshops on the changes of theft crimes *in the same county*. This section of the paper extends the analysis focusing on the presence of geographical spillover effects on crime.

We do so by estimating the following OLS regression:

$$y_{i,s,t} = \alpha_i + \gamma_t + \mu_{s,t} + X'_{i,s,t}\beta_0 + \#pawnc_{i,s,t}\beta_1 + \#pawnbord_{i,s,t}\beta_2 + \#pawncstate_{i,s,t}\beta_3 + \epsilon_{i,s,t}$$

where  $\#pawnbord_{i,s,t}$  is the number pawnshops per capita in  $i$ 's bordering counties and  $\#pawncstate_{i,s,t}$  is measure of the number of pawnshops per capita in  $i$ 's state. To avoid collinearity issues and dif-

---

<sup>24</sup>We also eliminate from the sample the top 10% - 20% and 30% of the most populous counties to check whether the result is driven by big cities. Results are stable across specifications and are not reported only for brevity considerations.

ficuity of interpretation, these two variables do not include the number of pawnshops in the county  $i$ .

Two important caveats to the analysis needs to be emphasized. First of all, given that our final dataset includes data on 2176 counties (70 % of the US total) and not all the counties in the United States, we observe these two measures with error. This inevitably leads to a downward bias in the estimated coefficients. A more serious econometric concern is instead related to the fixed effect structure of our estimating equation. The inclusion of two independent variables belonging to a different geographical unit of the dependent variable, potentially worsens the reliability of the estimate of these two coefficients. Table 10 shows the results of this specification.

Table 10:

The inclusion of these two new variables does not change the effect and the significance of the number of pawnshops in county  $i$  on larcenies and burglaries (first row of table 10). Interestingly, no effect of pawnshops in the neighboring counties is detected, while we find a large and significant coefficient of the number of pawnshops at the state level for larceny (21.60 significant at the 10 % level), for burglaries (15.1 significant at the 1% level) and for robberies (0.94 significant at 10%).

These results partly corroborate burglars' interviews that describe how the presence of stolen goods markets might strongly affect their choice of whether and where committing a theft. In fact, knowing that the probability of being caught increases while the stolen property are still in possession, burglars prefer to commit a theft at a maximum distance of half an hour by car from the resale point, (Sutton, 2010). Nevertheless, our results also seem to capture some strong geographical spillover effect, suggesting that burglars might take the risk of traveling far from the crime scene, plausibly to avoid suspects about the origin of the item or to outdistance the good from the place where it was stolen.

## 4 The Response to Gold Price: Evidence From a Quasi Natural Experiment

This section of the paper further addresses the endogeneity of pawnshops to crime, exploiting the exogenous rise in the price of gold as a quasi-natural experiment. Before going into the details of the research design, we will carefully describe the mechanism behind the importance of gold in our context. Then, we will move to the description of the identification strategy and to the analysis of the final results.

## 4.1 The Importance of Gold

### 4.1.1 The Demand side

Gold has always been the major determinant of pawnbrokers' profit function.<sup>25</sup> Bos et al. (2012) describe that in the US 34% of men and 63% of women used jewelry as pledge in pawn transactions, with gold representing roughly 80 percent of the value of all pledges.<sup>26</sup> Table 11, borrowed from Carter and Skiba (2012), reports the number of loans for each collateral category, the percentage of observations, and the average amount and standard deviation of the items pawned for each category. The sample of observations comes from a pawnshop lender in Texas between 1997 and 2002.

Table 11:

Forty-nine percent of pawnshops' loans in the dataset are collateralized with jewelry, with over half of the items in the jewelry category consisting of rings, including both men's and women's class and wedding rings. The next most popular category of pledges is televisions and electronics, including satellite dishes, stereos, and CD players. Individuals also commonly pawn tools, household items such as small appliances, sporting equipment, guns, musical instruments, and camera equipment. The average loan amount for loans collateralized by jewels is 96\$, a value only lower than guns and musical instruments. Moreover - as mentioned before - pawnbrokers do not accept motor - vehicles in their transaction.

But, what makes jewelry and - in particular - gold so profitable in pawnbrokers' activities? Along side the fact that gold is one of the most precious metal, a big part of the pawnbrokers' profits comes from the process of melting down the gold received by their clients through the "refinement" process. In fact, 90% of the times pawnbrokers sell their jewelry to a company that is known as a 'refiner.' A refiner will take all of the rings, necklaces, bracelets and other items and melt them. Truly professional outfits will then begin to remove impurities from the metals until they get something close to pure gold.<sup>27</sup> Hence, stolen items, easily transformed into an unrecognizable bar of precious metal, can disappear forever from the second - hand market (Sutton, 2010), ending

---

<sup>25</sup>The importance of gold in pawnbrokers' activities is reflected in its symbol: three spheres suspended from a bar. The three sphere symbol is attributed to the Medici family of Florence, Italy, owing to its symbolic meaning of Lombard. This refers to the Italian province of Lombardy, where pawn shop banking originated under the name of Lombard banking. The three golden spheres were originally a symbol medieval Lombard merchants hung in front of their houses, and not the arms of the Medici family. It has been conjectured that the golden spheres were originally three flat yellow effigies of byzants, or gold coins, laid heraldically upon a sable field, but that they were converted into spheres to better attract attention.

<sup>26</sup>Similar evidence is found in Comeau et al. (2011).

<sup>27</sup>Refiners typically have minimum quantities of metals that they will accept and work with. They normally work with several pounds of the material, so the direct link between clients and refiner can rarely happen. Information about this argument can be found online from a lot of different sources. As an example: <http://www.pawnerd.com/where-do-pawn-shops-sell-their-gold-and-silver/> or <http://www.economist.com/news/finance-and-economics/21591230-falling-price-gold-hurting-pawnbroking-business-hock-and-sinker>.

in the Bullion Market or in similar places.<sup>28</sup> This dynamic might hence potentially facilitate the burglars’ - or the pawnbrokers’ - attempt of safely getting rid of the stolen goods.

#### 4.1.2 The Supply Side

This strong demand for jewelry and gold in particular might influence criminal behavior. In fact, as in any other type of economic activity, the exact knowledge of the demand for stolen goods affects the type of items that are actually stolen. Even if most thieves have an ever-changing hierarchy of items that they prefer to steal (Sutton, 2010), crime statistics and victim surveys describe how the most commonly stolen items during burglaries are cash, jewelry and consumer electrical.<sup>29</sup> Table 12 shows the percentage of stolen items during burglaries. Police recorded crime data are from the Sandwell Metropolitan Borough Council area of the West Midlands (Burrell and Wellsmith, 2010).

Table 12:

Similarly, table 13 reports the percentage of stolen items during burglaries, by type of item in 1994, 2001 and 2011 in the United States. The category we are interested in is “personal portable objects” that include clothing, furs, luggage, briefcases, jewelry, watches, keys and other.

Table 13:

## 4.2 Research Design and Identification Strategy

We hence try to answer to the following question: does an increase in the expected benefits of crime, related to the exogenous raise in the gold price, cause relatively more theft crimes in counties with an higher predetermined concentration of pawnshops?

The underlying hypothesis is that the shift in the resale value of gold, exogenously determined by changes in the macroeconomic conditions, while potentially increasing burglars’ expected value of committing a theft uniformly in all counties, might cause relatively more theft crimes in counties with an higher predetermined concentration of markets potentially interested in acquiring gold products.

More in details, we estimate the following OLS equation:

$$y_{i,t} = \alpha_i + \gamma_t + X'_{i,t}\beta_0 + [\#pawns_{i,t=1997} * goldprice_t] \beta_2 + \epsilon_{i,t}$$

---

<sup>28</sup>The Bullion Market is a forum through which buyers and sellers trade pure gold and silver. The bullion market is open 24 hours a day and is primarily an over-the-counter market, with most trading based in London. The bullion market has a high turnover rate and most transactions are conducted electronically or by phone. Gold and silver derive their value from their industrial and commercial uses; they can also act as a hedge against inflation.

<sup>29</sup>Similar evidence is found in Fitzgerald and Poynton (2010), Sorensen (2011) and Walters et al. (2013).

where  $i$  indicates the county,  $s$  the state and  $t$  the year. Also in this case, the outcome of interest is the number of reported crimes, by county per year. The coefficient of interest is  $\beta_2$ , the effect on crime of the interaction between the initial concentration of the number of pawnshops per capita fixed in the first year of our sample (1997) and the gold price at time  $t$ . As in the first part of the paper, standard errors are clustered at the county level.

As in the first part of the paper, we use a within county specification including county fixed effect. A key role in this specification is played by the inclusion of year fixed effects, that partial out from the estimate the direct and uniform effect that the rise in gold price might have on the growth of theft crimes in all counties. Moreover, while arguably gold price is related to the stability of the global economic conditions, our specification uses a wide set of socio - economic controls related to the conditions of the local economy. As in the first part of the paper we include all controls and also the contemporaneous number of pawnshops. Furthermore, in order to control for the presence of other possible time - varying confounding factors, we add the interaction between each control fixed in year 1997 and the price of gold.<sup>30</sup>

Importantly for our analysis this specification - while providing a different angle from which analysing the role of stolen goods markets on crime - it also unambiguously addresses the reverse causality issue underlined in the first part of the paper.

#### 4.2.1 The Evolution of Gold Price

This study focuses on a 14 years period, from 1997 to 2010. During this period, gold price displayed some positive and negative oscillation, nevertheless raising its value of about 37% from 1997 to 2005. From 2006 to 2010 instead, gold price experienced an impressive increase of almost 200%.<sup>31</sup>

Figure 4.1:

This huge final spike poses some empirical issue that we address dividing the analysis in two periods:1997-2005 and 2006-2010. In particular, we are worried that the spike of almost 40% in the value of gold from 2006 to 2005 pushed other type of businesses such as jewelries and online refineries to increase the demand for gold products. In this case, the number of pawnshops, a measure of the underlying size of the market for gold, would suffer from a downward bias that would be amplified by the increase in measurement error after 2005.

---

<sup>30</sup> Results are qualitatively unchanged if we allow all the the controls to vary with the gold price.

<sup>31</sup>I use as unit of measurement the price of gold in US dollars (averaged over the entire year) per troy ounce. Data are freely downloadable at the following website: <http://www.gold.org>.

### 4.2.2 Results

Tables 14 and 15 reports the results, both for theft crimes and other crimes. The first row shows the effect of the contemporaneous number of pawnshops, while the second row reports the results of the interaction term of interest.

Table 14:

Overall, the estimates confirm the prediction that the effect of pawnshops on crime was strong and highly significant in the first 9 years of the sample rather than in the last 5. In particular, the main effect of pawnshops on larcenies and burglaries is 6.17 and 2.13, with both coefficients significant at the 1%. Conversely, these coefficients estimated in the second part of the panel are not precisely estimated. Furthermore, we detect a positive effect of the interaction term only for burglaries for both periods of the sample, of 1.10 and 0.30 both significant at the 10% level. To put this result into perspective, a one standard deviation increase in the initial concentration of pawnshops generates a 0.05 to 0.10 standard deviation increase in the effect of gold price on burglaries.

This time, the effect of the interaction term on larceny is not precisely estimated. These might be due to the fact that jewelry is a rare outcome for this generic type of theft, that includes thefts of bicycles, motor vehicle parts and accessories, shoplifting, pocket-picking, or the stealing of any property or article that is not taken by force. Once again, to further validate our analysis, no effect is detected on all other crimes (Table 15).

Table 15:

### 4.2.3 Robustness Checks

Table 16 shows the set of robustness checks for burglary between 1997 - 2005 (Panel A) and 2006 - 2010 (Panel B).

Table 16:

Column 1 reports the coefficient when we cluster standard errors at the state level, while in column 2 we show the results with double clustering at county - year level. For both the samples we lose precision in the estimates. As in the first part of the paper, column 3 shows the results when we weight the regression by the coverage indicator, in column 4 and 5 we eliminate respectively the counties in the top 1% of the pawnshops and population distribution. Coefficients are stable across all different specifications, with the only exception being column 4 panel B, with a p - value of 11%.

#### 4.2.4 Copper Thefts and the “Red Gold” Rush

The demand for copper from developing nations has generated an intense international copper trade. According to the FBI, copper thieves are exploiting this demand and the related spike in international prices by stealing and selling the metal to recyclers across the United States. Copper thieves are targeting electrical sub-stations, cellular towers, telephone land lines, railroads, water wells, construction sites, and vacant homes for lucrative profits.

In this last part of the paper we hence decide to perform a further falsification test, exploiting the fact that objects made by copper - while being heavily targeted by criminals - are not usually accepted in pawnshops’ transactions. Table 17 shows the results when we include in the specification the interaction between the price of copper and the initial concentration of pawnshops in the county.<sup>32</sup>

Table 17:

Adding this further control generates a multicollinearity between the two interaction term that reduces the significance of the interaction between gold price and pawnshops.<sup>33</sup> As we were expecting, we do not detect any positive effect of the initial concentration of pawnshops on the effect of copper price on burglaries. Interestingly, we instead detect a negative coefficient of 1.8 significant at the 1% level in the second part of the sample. While we do not want to overemphasize this result, we consider the substitutability across market for stolen goods as an extremely interesting venue for future research.

## 5 Concluding Remarks

This paper has offered a systematic empirical investigation of the effect of stolen goods markets on crime, an issue never properly explored in the existing literature on the determinants of crime. In particular, motivated by the richness of anecdotal evidence, we have looked at this issue through the lens of pawnshops, a business that has long been suspected of illicit trade. The endogeneity of pawnshops to crime has been addressed in multiple ways.

In the first part of the paper we have mainly exploited the panel properties of the data. Results confirm that the number of pawnshops is a strong and significant predictor of larcenies and burglaries. The findings are robust to extensive robustness checks, the clustering of standard errors at a different levels, the sensitivity to outliers, averaging the regression by a measure of the quality of the information available to the researcher and using a log - log model. The mechanism behind the findings is validated by numerous falsification tests on other crimes that disprove the possibility that pawnshops might affect crime through channels other than the transaction of stolen

---

<sup>32</sup>Data on historical copper price is obtained through the U.S. geological survey at: <http://www.usgs.gov/>

<sup>33</sup>The correlation between the price of gold and copper is 0.84.

goods. Moreover, we have detected the presence of geographical spillover effects on crime and we have analyzed the heterogeneity in the results across counties with a different population density.

In the second part of the paper we have exploited the exogenous shift in crimes' expected benefits using the raise in gold price - the main determinant of pawnbrokers' profit function - as a quasi natural experiment, where the intensity of the treatment is given by the initial concentration of pawnshops in the county. In particular, the identification strategy relied on the exogeneity of the interaction between the price of gold, constantly demanded by pawnbrokers in the form of jewels that are usually melted down to be transformed into a bar of the precious metal, and the initial allocation of the number of pawnshops in the county. A one standard deviation increase in the initial concentration of pawnshops generates a 0.05 to 0.10 standard deviation increase in effect of gold on burglaries. Also in this case, results are robust to a wide set of robustness checks and are corroborated by the presence of falsification tests on crimes that should not be affected by the presence of pawnshops.

This paper offers new direction of future research. A direct spin off of this work would be the analysis of other possible market for stolen goods, such as flea markets, junkyards and online web sites such as Ebay or Craigslist. Moreover, entering in the "black box" of the mechanism that links demand and supply of crime is critical for the understanding of criminal behavior. Two mechanisms might in fact play an important role in this context. On the one hand, the increase in the size of stolen goods' markets might increase crime by reducing the criminal expected probability of being arrested (negative deterrence effect). On the other hand, the increase in the level of competition in the resale market might push up prices, raising the expected resale value of the stolen item (price effect). Disentangling these two channels might help shaping specific policy interventions oriented to reduce the impact that the proliferation of stolen goods markets can have on crime. This and other interesting aspects are left for future research.

## Data Appendix

### Crimes Definition

1. Murder (criminal homicide): The willful (non negligent) killing of one human being by another.
2. Forcible rape: The carnal knowledge of a female forcibly and against her will.

3. Robbery: The taking or attempting to take anything of value from the care, custody, or control of a person or persons by force or threat of force or violence and/or by putting the victim in fear.

4. Aggravated assault: An unlawful attack by one person upon another for the purpose of inflicting severe or aggravated bodily injury. This type of assault usually is accompanied by the use of a weapon or by means likely to produce death or great bodily harm.

5. Burglary: The unlawful entry of a structure to commit a felony or a theft.

6. Larceny: The unlawful taking, carrying, leading, or riding away of property from the possession or constructive possession of another. Common types of larcenies include shoplifting, pocket-picking, purse snatching, theft of objects from motor vehicles, theft of bicycles and theft of items from buildings in which the offender has legal access.

7. Motor vehicle theft: The theft or attempted theft of a motor vehicle.

8. Arson: any willful or malicious burning or attempting to burn, with or without intent to defraud, a dwelling house, public building, motor vehicle or aircraft, personal property of another, etc.

### **Hierarchy Rule**

In some cases, a single incident may have consisted of two distinct offenses. For example, during the course of a robbery, a victim may have been fatally shot. In cases in which multiple offenses are committed by the same offender against the same victim during a given felonious act, the hierarchy rule is employed to determine how the crime is classified. A crime is classified according to the most serious offense committed. Importantly, the hierarchy rule does not apply to the offense of arson. In fact, when arson is involved in a multiple offense situation, the reporting agency must report two part I offenses, the arson as well as the additional part I offense.

\*\*\* p<0.01, \*\* p<0.05, \* p<0.1. Standard errors are clustered at the county level. The number of pawnshops and reported crimes are expressed in per capita terms. The unit of analysis is the county. Theft Crimes include: larcenies, robberies, burglaries and motor – vehicle thefts. Other crimes include: murders, rapes, aggravated assaults and arsons. The table shows the evolution of the coefficients when fixed effects and controls are included. The most complete specification (with county FE, year FE, State linear trends and all controls) is shown in column 5 and 10.

County FE	YES	YES	YES	YES	YES	YES
Controls	ALL	ALL	ALL	ALL	ALL	ALL

\*\*\* p<0.01, \*\* p<0.05, \* p<0.1. All the standard errors are clustered at the county level. In both columns 1, both for larcenies and burglaries, we show the baseline specification with the contemporaneous number of pawnshops. In columns 2 we add the number of pawnshops per capita, at t-1. Finally, in columns 3 we include the number of pawnshops per capita at t-2.

TABLE 7  
Crimes' lagged structure (Pawnshops as an outcome)

	(1)	(2)	(3)	(4)	(5)	(6)
	Larcenies			Burglaries		
Contemporaneous Crime	0.25*** (0.9)	0.12 (0.08)	0.11 (1.330)	0.46** (0.20)	0.18 (0.17)	0.09 (0.18)
Crime (T-1)		0.17** (0.08)	0.10* (1.318)		0.29* (0.17)	0.21 (0.15)
Crime (T-2)			0.11 (1.39)			0.11 (0.17)
Year FE	YES	YES	YES	YES	YES	YES
State Trends	YES	YES	YES	YES	YES	YES
County FE	YES	YES	YES	YES	YES	YES
Controls	ALL	ALL	ALL	ALL	ALL	ALL

\*\*\* p<0.01, \*\* p<0.05, \* p<0.1. All the standard errors are clustered at the county level. The outcome variable is the number of pawnshops per capita in the county at time t. In the first three columns the main regressor is the number of larcenies. In the last three columns the coefficient of interest is the number of burglaries.

TABLE 8  
Robustness Checks

	(1)	(2)	(3)	(4)	(5)
Panel A - Larcenies					
Pawnshops per capita	4.57** (2.1)	4.57*** (1.59)	4.37*** (1.569)	4.94*** (1.761)	4.53*** (1.68)
Panel B - Burglaries					
Pawnshops per capita	1.51** (0.65)	1.51** (0.73)	1.48** (0.62)	1.6** (0.68)	1.51** (0.65)
Year FE	YES	YES	YES	YES	YES
State Trends	YES	YES	YES	YES	YES
County FE	YES	YES	YES	YES	YES
Controls	ALL	ALL	ALL	ALL	ALL

\*\*\* p<0.01, \*\* p<0.05, \* p<0.1. Panel A shows the results for larcenies, while panel B shows the results for burglaries. Column 1 shows the results when we cluster at the state level, while in column 2 we cluster at the county/year level. In column 3 we perform a weighted regression using as weight the FBI coverage indicator. In column 4 we eliminate from the sample the counties in the top 1% of the pawnshops' per capita distribution. In column 5 we eliminate from the sample the counties in the top 1% of the population distribution.

TABLE 9  
Heterogeneity in the Results: Density

	(1) Larcenies		(2) Burglaries		(3) Robberies		(4) M/V Thefts

Adjusted R-squared	0.85	0.799	0.912	0.842
Year FE	YES	YES	YES	YES
State Trends	YES	YES	YES	YES
County FE	YES	YES	YES	YES
Controls	ALL	ALL	ALL	ALL

\*\*\* p<0.01, \*\* p<0.05, \* p<0.1. All the standard errors are clustered at the county level. Each column shows the results from a different regression where the outcome variable is the number of reported crimes (per capita) in the county. In each regression we include the number of pawnshops in the county, the number of pawnshops in the bordering counties (excluding the number of pawnshops in the county where crime is measured), the number of pawnshops in the state (excluding the number of pawnshops in the county where crime is measured).

Table 11  
Collateral by Category (Carter and Skiba, 2012)

Category	Number of Observations	Percentage of Observations	Average Loan Amount	Standard Deviation
<b>Jewelry</b>	199,288	<b>49.98%</b>	\$96.28	105.02
TVs/Electronics	126,297	31.68%	\$58.80	62.34
Tools/Equipment	31,600	7.93%	\$50.18	60.67
Household Items	10,552	2.65%	\$42.92	44.7
Missing	7,833	1.96%	\$63.75	72.54
Guns	7,734	1.94%	\$146.97	98.75
Instruments	7,700	1.93%	\$116.92	104.66
Camera/Equipment	4,052	1.02%	\$75.85	77.87
Misc	3,666	0.92%	\$51.50	62.46

Table 11 reports the number of loans for each collateral category, the percentage of observations, and the average amount and standard deviation of the items pawned for each category. All amounts are in 2002 dollars. The sample of observations is from a pawnshop lender in Texas between 1997 and 2002, (Carter and Skiba, 2012).

Table 12 (Burrel and Wellsmith, 2010)

Items stolen during burglaries

Cash	40%	Documents	5%
<b>Jewellery</b>	<b>31%</b>	Ornaments	5%
Audio	25%	Food	5%
VCR	17%	Tools	5%
TV	17%	Furniture	3%
Personal	12%	Cigarettes	3%

\*\*\* p<0.01, \*\* p<0.05, \* p<0.1. All the standard errors are clustered at the county level. This table shows the results of the specification where pawnshops per capita and the interaction between pawnshops in 1997 (the first year of the sample) and Gold price at time t are included. We also include the interactions between all controls fixed in the year 1997 and the gold price at time t, all controls, county and year fe.

Table 16  
Robustness Checks Burglaries

	(1)	(2)	(3)	(4)	(5)
Panel A – 1997-2005					
Pawnshops (t0)*Gold Price (t)	1.10 (0.66)	1.10 (0.70)	1.18** (0.58)	1.29** (0.65)	1.09* (0.58)
Panel B – 2006-2010					
Pawnshops (t0)*Gold Price (t)	0.30 (0.18)	0.30 (0.19)	0.28* (0.15)	0.27 (0.18)	0.29* (0.16)

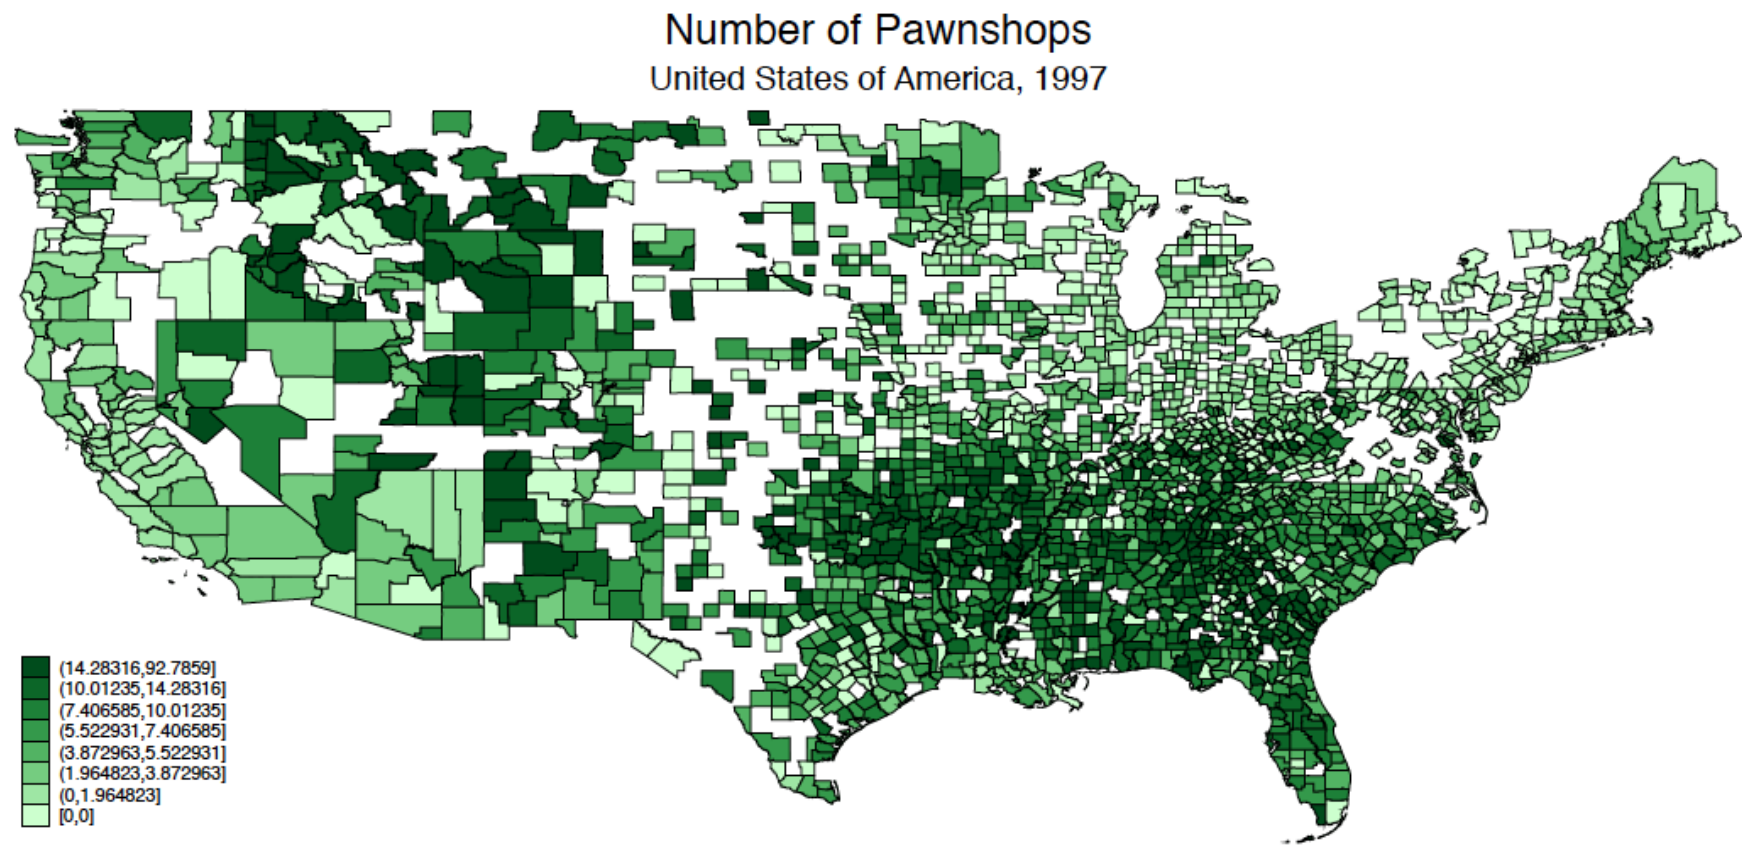

\*\*\* p<0.01, \*\* p<0.05, \* p<0.1. Panel A shows the results for larcenies, panel B shows the results for burglaries, panel C show the results for Robberies. Column 1 shows the results when we cluster at the state level, while in column 2 we cluster at the county/year level. In column 3 we perform a weighted regression using as weight the FBI coverage indicator. In column 4 we eliminate from the sample the counties in the top 1% of the pawnshops' per capita distribution. In column 5 we eliminate from the sample the counties in the top 1% of the population distribution.

TABLE 17  
Falsification Test on Copper Price

	(1)	Burglaries	(2)
	1997-2005		2006-2010
Pawnshops (t0)*Gold Price (t)	1.26 (0.95)		0.20 (0.16)
